PROJECT OVERVIEW
RECYCLED WATER STUDY

1. INTRODUCTION

This report presents the results of a study to evaluate how recycled water used for irrigation may affect groundwater resources in the Santa Clara and Llagas Groundwater Subbasins in Santa Clara County. The study was completed by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD), in five phases which are presented in Volumes I through V of this report. The recycled water study includes a series of evaluations to determine the potential for changes to groundwater quality from using recycled water for irrigation. The study includes a literature review, data analysis, soil model, bench test, pilot study, and an assessment of soil aquifer treatment capacity and groundwater degradation potential. In addition to these assessments, the study develops proposed recycled water irrigation screening levels, best management practices, and ongoing monitoring requirements.

1.1. Purpose

The use of recycled water for irrigation presents one of the best available opportunities for water conservation efforts for Santa Clara County. The water source is renewable and readily available, with a distribution network in place for many areas. However, previous studies have identified potential impacts to groundwater resulting from the use of recycled water. The overall goal of this study is to compile and obtain information that can be used to apply recycled water for irrigation in a manner that maintains protection of groundwater resources. This goal is consistent with objectives of the SCVWD and the California State Water Resources Control Board (SWRCB).

1.1.1. SCVWD Objectives

According to the Santa Clara Valley Water District Act, SCVWD objectives related to groundwater management are to recharge the groundwater basin, conserve water, increase water supply, and to prevent waste or diminution of the SCVWD's water supply, including the groundwater. The SCVWD Board of Directors has adopted policies to expand the use of recycled water and to aggressively protect groundwater quality. One of the SCVWD's water use efficiency programs is to increase use of recycled water which promotes effective use of water supply. The SCVWD has been involved in water recycling since the 1970s. Recycled water use in the county has grown from about 1,000 acre-ft in 1998 to over 15,000 acre-ft in 2008. The SCVWD implemented this study to gain a better understanding of how recycled water used for irrigation may affect groundwater quality so that measures may be implemented to ensure that future use of recycled water will continue to increase water supply while protecting groundwater quality.

1.1.2. State Water Resources Control Board Objectives

In May 2009, the SWRCB adopted a Recycled Water Policy, which includes a goal for California to increase recycled water use above 2002 levels by at least one million acre feet per year (afy) by 2020 and by at least two million afy by 2030. The expanded use of recycled water use for irrigation would assist in meeting these goals.

SWRCB's *Statement of Policy with Respect to Maintaining High Quality Waters in California* (SWRCB Resolution No. 68-16, also known as the State Antidegradation Policy) establishes that current groundwater quality will not be degraded to the point where beneficial uses are impacted. Therefore, the expanded use of recycled water for irrigation needs to be implemented in a manner that protects the quality of groundwater.

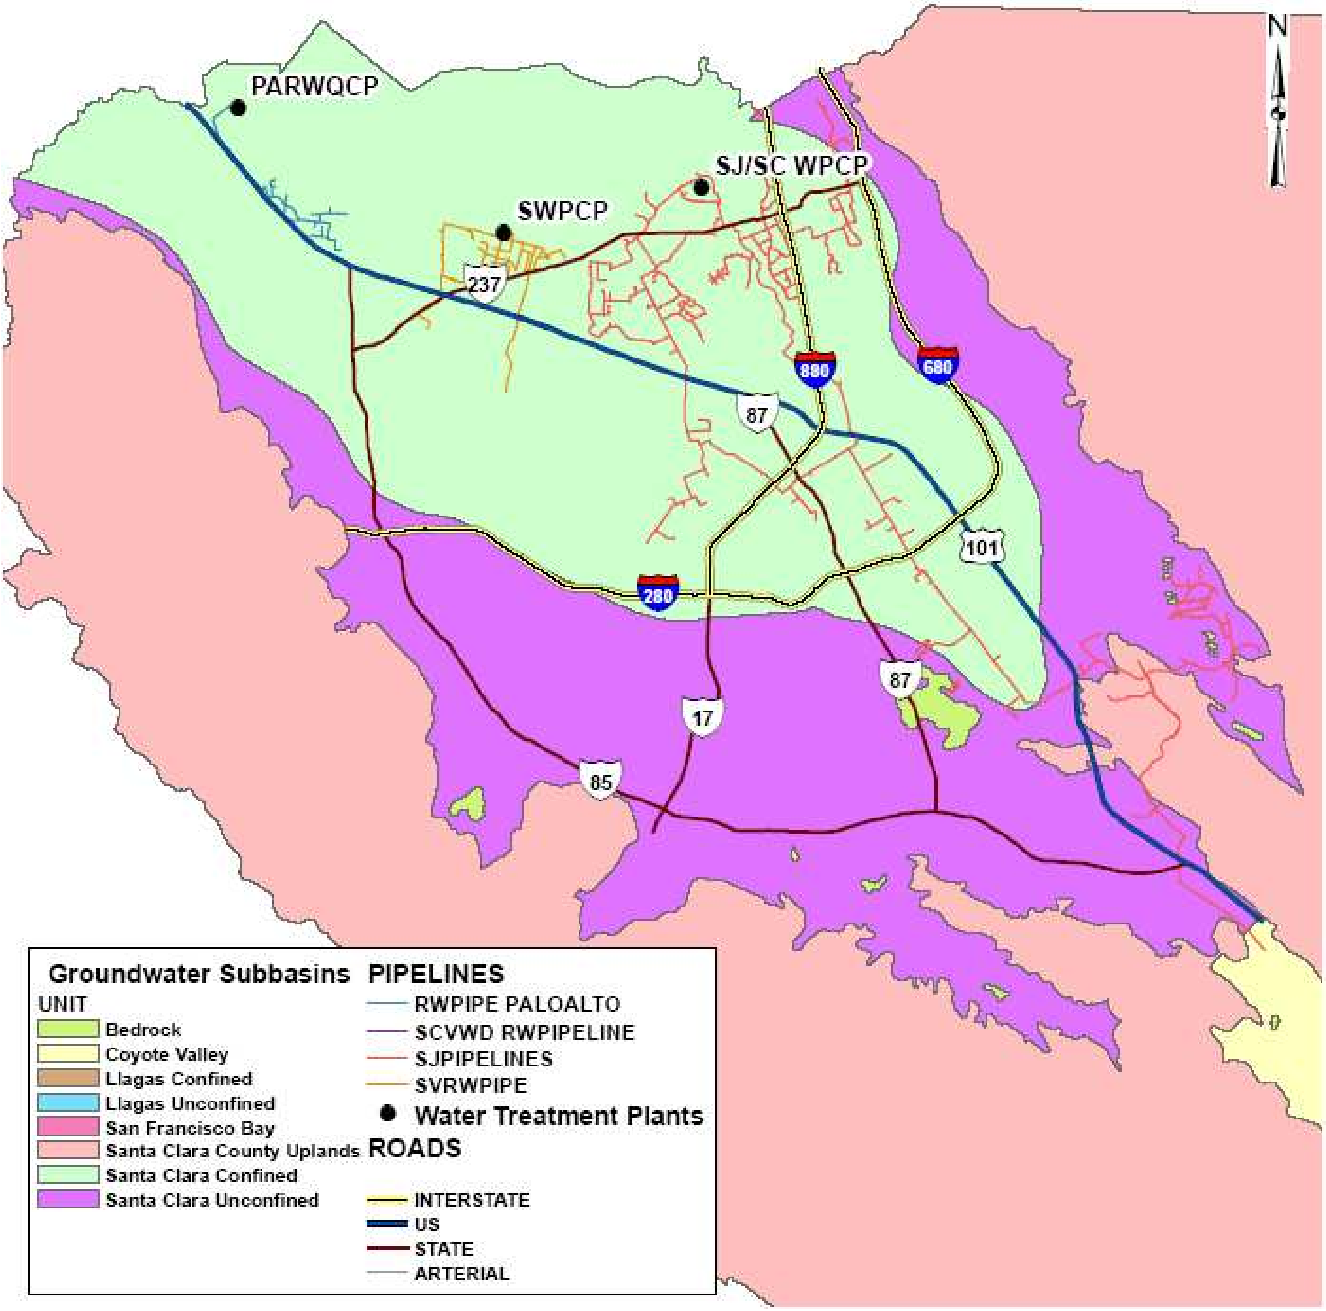
This study is designed to help expand the use of recycled water in Santa Clara County while protecting groundwater quality.

1.2. Project Study Area

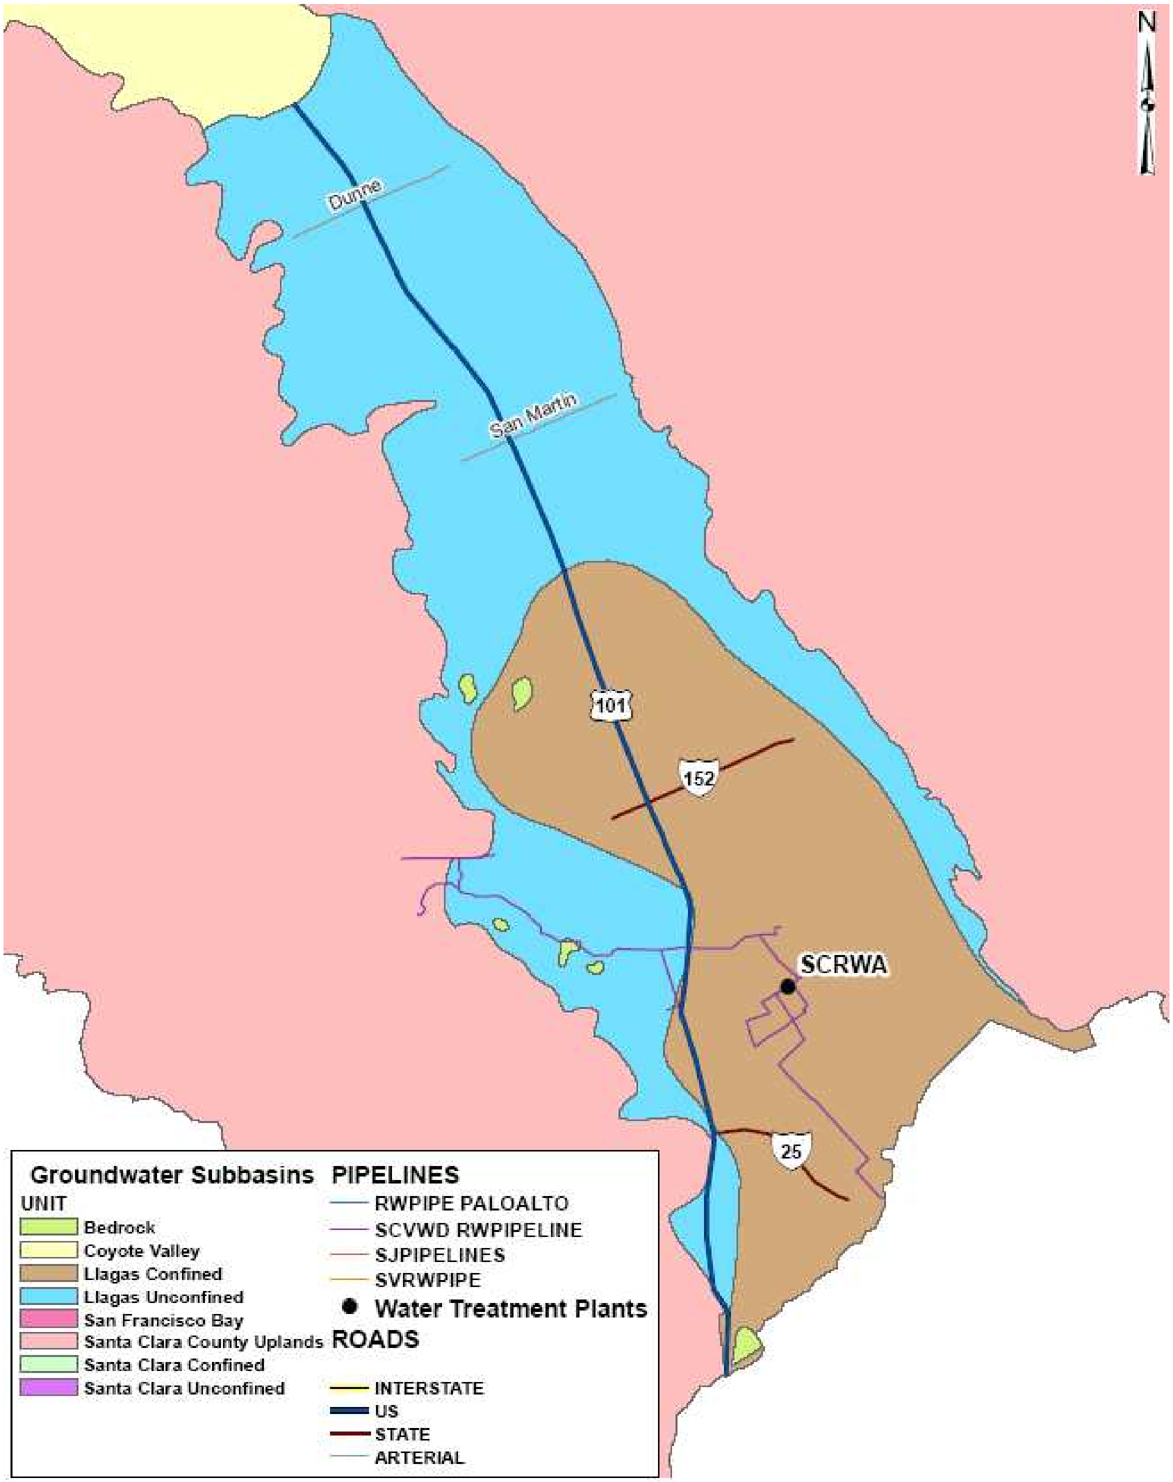
The study area for this project is defined by the Santa Clara and Llagas Groundwater Subbasins in Santa Clara County, California. The Santa Clara and Llagas Groundwater Subbasins contain both confined and unconfined areas. With few exceptions, current use of recycled water for irrigation in these groundwater subbasins is limited to confined areas, where a protective aquitard prevents direct percolation from the surface to groundwater. The overall goal of this study is to evaluate how the expanded use of recycled water for irrigation may affect groundwater quality in the Santa Clara and Llagas Subbasins. Potential impacts include changes in soil hydraulic conductivity and changes in groundwater quality.

The study area includes four sources of recycled water: Palo Alto Regional Water Quality Control Plant (PARWQCP), Sunnyvale Water Pollution Control Plant (SWPCP), San Jose/Santa Clara Water Pollution Control Plant (SJ/SC WPCP), and the South County Regional Wastewater Authority (SCRWA) in Gilroy. These four sources produce tertiary treated effluent that is currently being used within the study area. The figures below display the treatment plants in the study area and the current recycled water pipeline network.

Recycled Water Sources in Santa Clara Groundwater Subbasin:



Recycled Water Sources in Llagas Groundwater Subbasin:



1.3. Report Organization

This study includes several technical evaluations, which are organized into five volumes as follows:

1.3.1. Volume I: Literature Review and Data Analysis

The first phase of this study was a literature review, which assessed relevant recycled water studies, including those previously conducted by SCVWD. The literature review pooled current knowledge related to the fate and transport of recycled water, investigated the effects on soil permeability, identified areas where further investigation is needed, and identified investigative techniques to be used for the remainder of the study. The review also compiled a comprehensive list of constituents that have been previously detected in recycled water sources. The literature review is documented in Volume I of this report.

The data analysis is a review of the water quality of recycled water and groundwater in the study area. The available data analyzed, which originated from the District database, included groundwater samples from the Santa Clara and Llagas Subbasins and recycled water samples from the four treatment plants: PARWQCP, SWPCP, SJ/SC WPCP, and SCRWA. The analysis identified major constituents in recycled water and compared the quality to groundwater quality. The data analysis is documented in Volume I of this report.

The literature review and data analysis were used to determine which constituents should be sampled during the course of the study, including the bench test and pilot study.

1.3.2. Volume II: Soil Attenuation Model and Bench Test

As the next phase of the study, a numerical soil attenuation model was used to estimate the transport of tertiary treated recycled water constituents from the surface to groundwater. The one-dimensional model was run with scenarios in different soil types, with four recycled water constituents: bromodichloromethane, chloroform, N-nitrosodimethylamine (NDMA), and m-xylene. The model determined the attenuation of these constituents over time and depth. In addition, a sensitivity analysis was done to test the sensitivity of the different input parameters in the model. The soil attenuation model is documented in Volume II of this report.

A laboratory bench test was constructed to obtain actual physical and chemical data on recycled water transport through a range of local soil types in a controlled environment. Tertiary treated recycled water from the SJ/SC WPCP and SCRWA was applied to two-inch diameter soil cores for four months. The bench test was used to determine the permeability of varying soil cores with recycled water, quantify changes in the soil hydraulic conductivity from use of recycled water, and quantify the attenuation of recycled water constituents from percolation through the soil cores. The bench test is documented in Volume II of this report.

1.3.3. Volume III: San Jose Pilot Study

A full-scale pilot study of irrigation using tertiary treated recycled water from the SJ/SC WPCP was implemented and monitored at a site in San Jose, California. The selected pilot study site was a commercial office property with large areas of turf and other landscaping. The subsurface and irrigation characteristics were similar to many other sites within the study area that would be considered for future recycled water use. The pilot study monitored the quality of the irrigation water, pore water, and shallow groundwater to a depth of 30 feet over an 18-month period to evaluate the impact of recycled water constituents. The pilot study is documented in Volume III of this report.

1.3.4. Volume IV: Evaluation of Potential Impacts

Extrapolating data from the previous findings of the study, the soil aquifer treatment capacity and groundwater degradation potential were geographically rated, in a one to ten rating system (with ten being the worst case scenario), across the study area. Soil aquifer treatment capacity was defined in this study as the ability of the subsurface to naturally treat contaminants and is dependent on hydrogeological characteristics of a given area. The groundwater degradation potential was defined as the potential for groundwater to be impacted by recycled water used for irrigation based on the soil aquifer treatment capacity and the quality of the recycled water applied for a given area. The evaluation used is an adaptation of EPA's DRASTIC method utilizing geographic information system (GIS) software. The evaluation is documented in Volume IV of this report.

1.3.5. Volume V: Proposed Recycled Water Irrigation Screening Levels, Best Management Practices, and Ongoing Monitoring Recommendations

This volume of the report includes proposed recycled water irrigation screening levels (PRWISLs), best management practices (BMPs), and ongoing monitoring recommendations. PRWISLs are advisory levels for recycled water quality and are defined as the maximum concentration of a recycled water constituent at which the minimal groundwater degradation potential could be achieved. BMPs are effective and practical methods for using recycled water in irrigation that provide successful protection to groundwater resources. BMPs evaluated in this report are specific to recycled water use as an irrigation source for landscaping with the goal of minimizing the degradation of groundwater resources. Ongoing monitoring recommendations are established to provide timely recognition of any adverse changes in groundwater quality due to application of recycled water.

1.4. Review Process

This study was peer reviewed by an expert review panel consisting of three leading experts in recycled water and contaminant fate and transport. The expert review panel provides quality assurance in each phase of the study through technical guidance and direction. The following are the members of the expert review panel:

Dr. David L. Sedlak
Professor at Department of Civil and Environmental Engineering, University of California Berkeley

Dr. Joseph P. LeClaire
Principal Scientist at Wildermuth Environmental, Inc.

Jill Robinson Haizlip
Senior Geochemist at Geologica

2. FINDINGS AND MAJOR CONCLUSIONS

Overall, the findings from the study have indicated that within the Santa Clara and Llagas Subbasins, recycled water can be used as an irrigation source in a manner that protects the groundwater quality. However, the implementation of recycled water for irrigation should proceed with some considerations in order to minimize the potential groundwater degradation. The study has shown from the literature review, bench test, and the pilot study that there are numerous constituents found in recycled water, many of which have different fate and transport characteristics. Some constituents were observed in the study to not pose an impact to groundwater while others, such as perfluorochemicals (PFCs) and NDMA, prompt some concern due to their detection in shallow groundwater during the pilot study. It was determined from the soil aquifer treatment (SAT) capacity and groundwater degradation potential (GWDP) maps of the Santa Clara and Llagas Subbasins that the most ideal areas for recycled water irrigation are generally in the areas with a confining layer and deep groundwater. These areas are found in the northern section of the confined areas in the Santa Clara Subbasin and in the southern section of the confined areas in the Llagas Subbasin.

In light of the study findings, best management practices (BMPs), ongoing monitoring recommendations, and proposed recycled water irrigation screening levels (PRWISLs) were developed. Major best management practices (BMPs) include careful site selection (considering soil aquifer treatment capacity and other methods) and consideration of improved recycled water quality (i.e. dilution, source control, or additional treatment) particularly where recycled water quality is worse than PRWISLs. Ongoing monitoring is intended to provide timely recognition of any adverse changes in groundwater quality due to application of recycled water.

2.1. Potential Threat Values

Below is a table summarizing the potential threat to groundwater with respect to each constituent based on findings from the pilot study and bench test. Each constituent is given a rating between 1 and 5, with 5 representing the highest threat. The criteria for assigning each threat are the observed attenuation of the constituent in the pilot study and bench test and the type of constituent. In general, the greater the overall attenuation behavior displayed from the bench test and pilot study the lower the threat is. Also considered is whether the constituent is naturally occurring (which would results in a lower threat) or has known health impacts (resulting in a higher threat). The type of constituent can range from general water quality parameters like alkalinity and dissolved oxygen, to emerging contaminants such as NDMA and PFCs. The threat assigned for each constituent below is a culmination of these factors. While general water quality parameters are evaluated here in terms of threat, they are useful as indicators for water stability.

Some monitored constituents were not consistently detected in the recycled water source during the study. Since the attenuation of those constituents could not be evaluated, the threat value is assigned as inconclusive. Further monitoring of recycled water sources is needed to determine whether those constituents are sufficiently present to pose a threat to groundwater.

In addition to the threat value, the table includes a recommendation on whether further monitoring of each constituent is warranted. Constituents that are recommended for further monitoring are those with a threat value of three or higher or regarded as inconclusive. Bromide, which is regarded as a good tracer for recycled water, is also recommended for further monitoring.

Constituent	**Potential Threat**	**Findings**	**Recommend for Further Monitoring?**
ORP	1	ORP is a general water quality parameter. Measurements of ORP in the bench test and pilot study suggest no major shifts in redox conditions.	N
pH	1	The pH is a general water quality parameter. The pH was near neutral throughout the pilot study and bench test. Similarity of pH across depth has indicated stable conditions in each test.	N

Chlorine, Total	1	Concentrations of chlorine were higher in groundwater than in recycled water and pore water in the pilot study.	N
Dissolved Oxygen	1	DO is a general water quality parameter. DO was 0.01 mg/L or above across depth in the pilot study indicating that anoxic conditions were unlikely. Samples from the bench test indicated oxic conditions.	N
Alkalinity, Total	1	Alkalinity is a general water quality parameter monitored in the bench test and pilot study. A greater alkalinity in the pore water equates to more stability in pH conditions.	N
Bicarbonate Alkalinity	1		N
Boron	3	Boron removal was not well observed in the bench test or pilot study.	Y
Calcium	2	Calcium concentrations are greater in the subsurface than in the recycled water in the pilot study.	Y (See SAR)
Magnesium	2	Magnesium concentrations are greater in the subsurface than in the recycled water in the pilot study.	Y (See SAR)
Sodium	4	Sodium is directly related to SAR, as well as having a direct potential effect on groundwater.	Y
Sodium Adsorption Ratio (SAR)	4	The SAR may indicate impact to soil drainage from clay swelling as a result of recycled water application when the SAR in the recycled water is higher than the SAR of the previous irrigation source.	Y
Potassium	1	Potassium data from bench test and pilot study suggested good removal.	N
Sulfate	3	In the pilot study, sulfate increased in concentration in the pore water, likely due to the contribution from soil and fertilizer. Sulfate concentration in groundwater was relatively stable in the pilot study. In the bench test, removal was not well observed. The constituent also contributes to the total dissolved solids.	Y
Nitrite	2	Nitrate/Nitrite data showed removal with depth in the pilot study. The mechanism is suspected to be attenuation by root uptake pathway.	N
Nitrate	2		N
Chloride	4	Chloride over time has shown an increasing trend in concentrations in groundwater and pore water in the pilot study. At the end of the pilot study, chloride had not yet reached stable conditions. Attenuation of chloride in the bench test was not well observed. The constituent also contributes to the total dissolved solids.	Y

Total Organic Carbon (TOC)	2	TOC was decreased by microbial activity and adsorption to soil in the pilot study and bench test; groundwater was relatively stable in pilot study. The bench test findings were consistent with the pilot study.	N
Total Filterable Residue at 180C (TDS)	3	Although TDS in the pilot study in groundwater appeared relatively stable, levels have been observed above secondary drinking water standards in both the baseline and subsequent events. The TDS in recycled water and lysimeters are also above secondary drinking water standards. In the bench test, attenuation was not well observed.	Y
Dissolved Organic Carbon	2	DOC was decreased by microbial activity and adsorption to soil in the pilot study and bench test; groundwater was relatively stable in pilot study. The bench test findings were consistent with the pilot study.	N
Bromodichloromethane (THM)	2	Bromodichloromethane was removed in the vadose zone in the pilot study. Bromodichloromethane was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.	N
Bromoform (THM)	2	Bromoform was removed in the vadose zone in the pilot study. Bromoform was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.	N
Chloroform (THM)	2	Chloroform was removed in the vadose zone in the pilot study. Chloroform was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.	N
Dibromochloromethane (THM)	2	Dibromochloromethane was removed in the vadose zone in the pilot study. Dibromochloromethane was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.	N
Carbon Tetrachloride (VOC)	1	Carbon tetrachloride was not detected in recycled water in pilot study or bench test. The constituent was also categorized as having minimal potential impact in Volume I.	N
Xylenes, Total (VOC)	1	Xylenes were not detected in recycled water in pilot study or bench test. The constituent was also categorized as having minimal potential impact in Volume I.	N
Additional 8010-list VOCs	1	VOCs were not detected in recycled water in the pilot study or bench test. VOCs excluding xylene and carbon tetrachloride were also not detected in the data analysis of Volume I.	N

Haloacetic Acids (HAA6):	4	HAA6 were not observed in the baseline groundwater samples, but were observed in the applied recycled water, pore water, and groundwater during the pilot study. In the bench test, HAA6 attenuation was not well observed. HAA6 are also anthropogenic compounds.	Y
Bromochloroacetic Acid			
Dibromoacetic Acid			
Monobromoacetic Acid			
Monochloroacetic Acid			
Trichloroacetic Acid			
Heterotrophic Plate Count	3	Growth was present in pore water and groundwater in the pilot study. Growth was also observed in the bench test. Attenuation was not observed.	Y
Coliforms, Total	3	Growth was present in pore water and groundwater. Growth was also observed in the bench test. Attenuation was not observed.	Y
Fecal Coliforms	3	Fecal Coliforms were not present in groundwater during the pilot study. In the bench test, fecal coliforms were not frequently detected. Attenuation was not well observed.	Y
E. Coli	Inconclusive	E. Coli was minimally detected in recycled water in the pilot study. In the bench test, E. coli was not frequently detected. Therefore the attenuation behavior could not be examined. The constituent may be present in the other recycled water sources in the study area.	Y
N-Nitroso Dimethylamine (NDMA)	5	NDMA was not observed in the baseline groundwater samples, but was observed in the applied recycled water, pore water, and groundwater during the pilot study. The majority of attenuation of NDMA could potentially be from volatilization in the vadose zone and/or biotransformation in the soil. In the bench test, NDMA attenuation was not strongly observed. NDMA is an emerging contaminant.	Y
Perfluorochemicals	5	PFCs were not observed in the baseline groundwater samples, but were observed in the applied recycled water, pore water, and groundwater during the pilot study. Similarly, in the bench test, some PFCs were observed in the effluent but not in the influent. There is potential for PFC formation from precursors. PFCs are emerging contaminants.	Y
Phosphate	1	Phosphate removal was observed in the pilot study and bench test. Mechanisms that caused removal of phosphates are suspected to be the root uptake pathway and precipitation.	N
Ethylenediaminetetraacetic acid (EDTA)	3	EDTA was not detected in recycled water in the pilot study. In the bench test attenuation was not consistently observed.	Y

Surfactants (MBAS)	3	Surfactants were minimally detected in recycled water in the pilot study. In the bench test attenuation was not consistently observed.	Y
Bromide	2	Removal of bromide in the vadose zone is low in the pilot study; however the degree of toxicity of bromide is low. Together with chloride bromide can be used as a tracer for recycled water.	Y
Nitrilotriacetic acid (NTA)	Inconclusive	NTA was not detected in the pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.	Y
Perchlorate	Inconclusive	Perchlorate was not detected in recycled water during the pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.	Y
Cyanide	Inconclusive	Cyanide was minimally detected in pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.	Y
Terbuthylazine	Inconclusive	Terbuthylazine was minimally detected in recycled water in pilot study and bench test. Therefore the attenuation behavior could not be fully examined. The constituent may be present in the other recycled water sources in the study area.	Y

2.2. Soil Aquifer Treatment Capacity

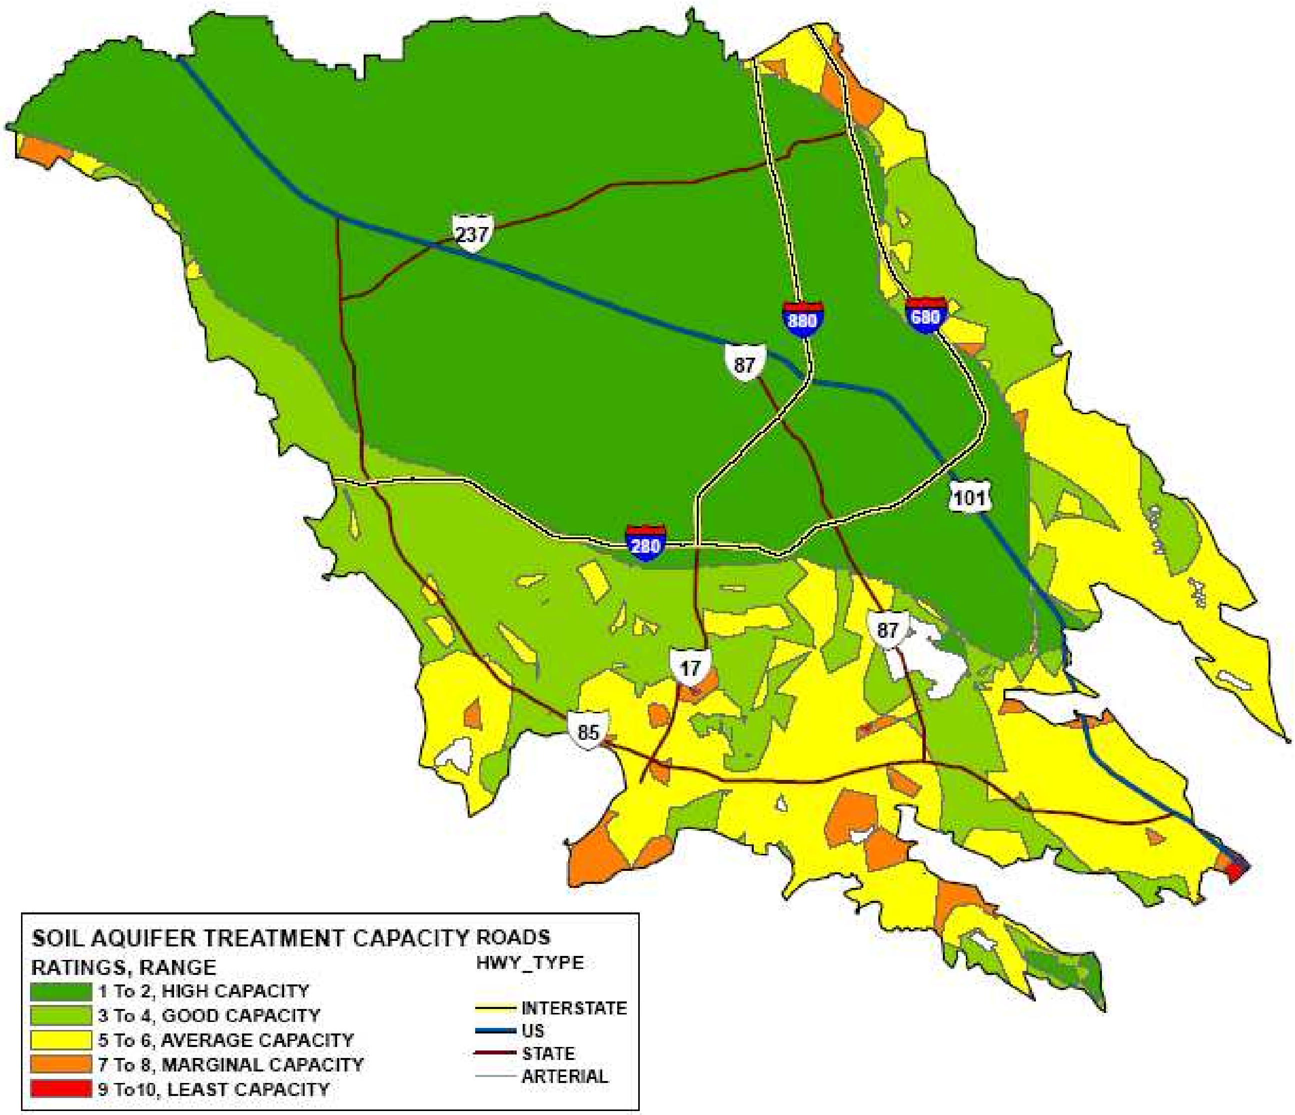
For this study, soil aquifer treatment capacity is defined as the ability of the vadose zone soil to naturally treat contaminants. The study focuses on contaminants found in recycled water. Mechanisms to lower the concentrations of contaminants include but are not exclusive to volatilization, dispersion, diffusion, sorption, precipitation, ion exchange, oxidation-reduction, transformation, and filtration. Soil aquifer treatment capacity is established from the hydrogeological characteristics of a given area.

Soil aquifer treatment capacity was determined for the entire study area on a scale of 1 to 10, with 1 representing areas with physical characteristics that are most ideal for the application of recycled water and protection of groundwater quality and 10 representing the least ideal areas.

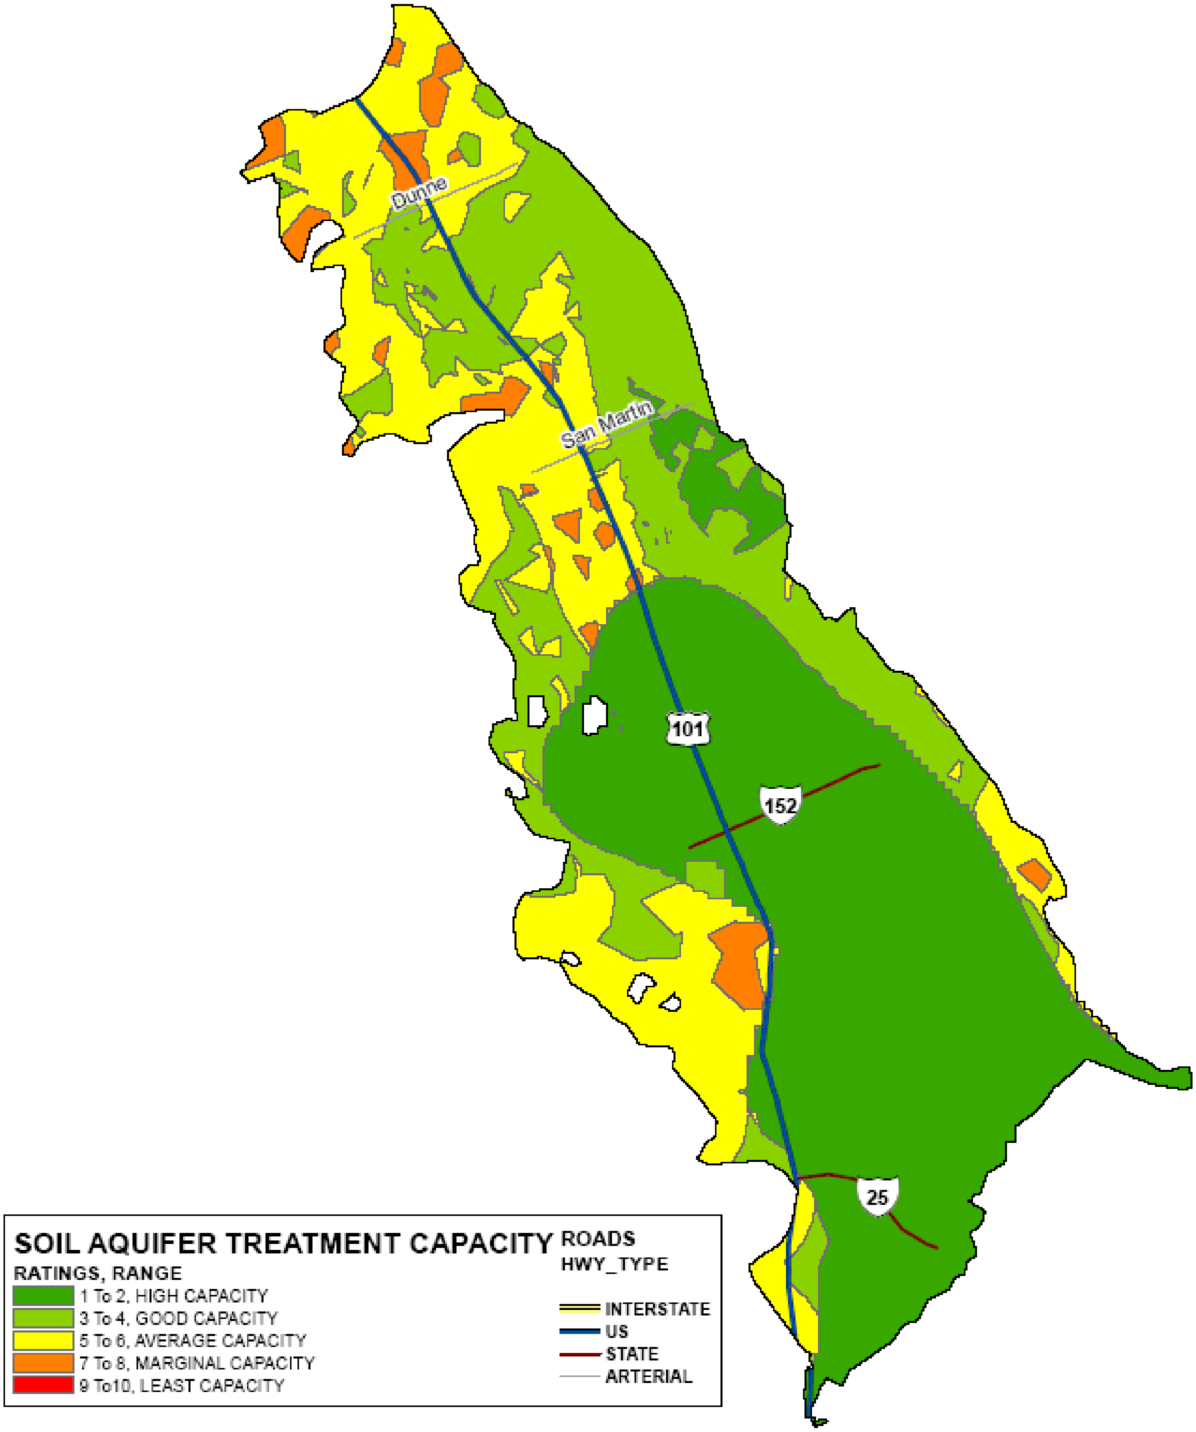
The SAT rating in the Santa Clara Subbasin ranges from 1 to 10. In the Llagas Subbasin, the SAT rating ranges from 1.5 to 9.5. In both subbasins, the confined areas were determined to have relatively high capacity due to the confining layer and deep groundwater. The unconfined areas were largely of good or average capacity. Only a few areas in the unconfined areas were regarded as having relatively marginal capacity and even fewer areas were regarded as least capacity. Areas with a lower rating tended to be characterized with a shallow depth to water and a coarse grain size distribution in the subsurface. The confining layer and deep depth to groundwater are characteristics of the most ideal areas within the study area for soil aquifer treatment capacity.

The following figures present the soil aquifer treatment capacity distribution in Santa Clara and Llagas Groundwater Subbasins.

Soil Aquifer Treatment Capacity for the Santa Clara Groundwater Subbasin:



Soil Aquifer Treatment Capacity for the Llagas Groundwater Subbasin:



2.3. Groundwater Degradation Potential

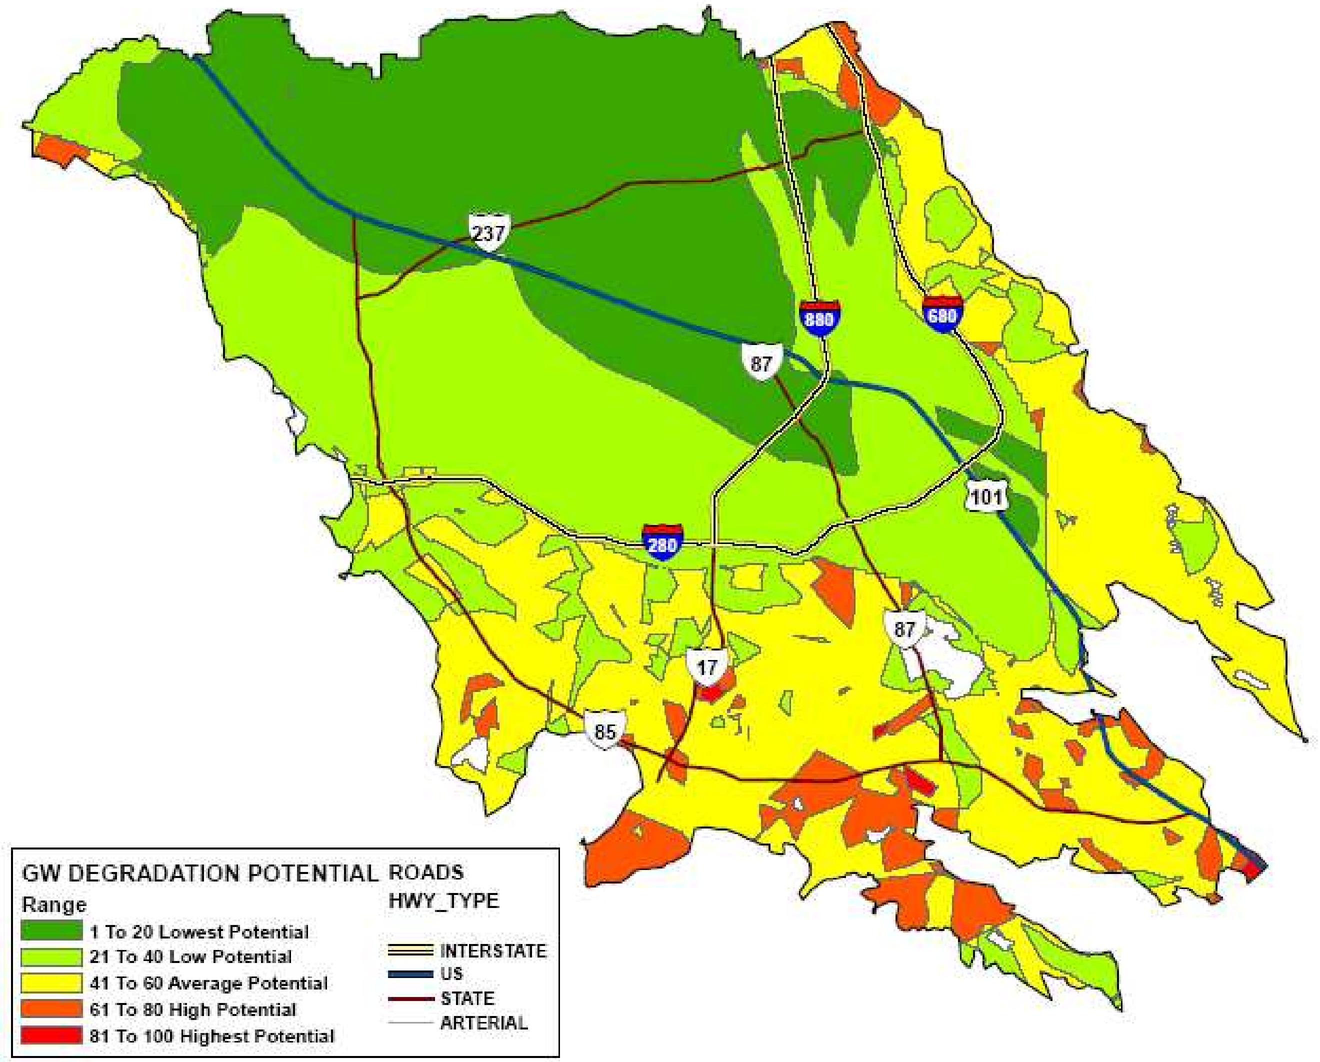
Groundwater degradation potential is defined as the potential for groundwater to be impacted by recycled water used in irrigation. Groundwater is regarded as degraded when the quality is worse than current groundwater quality as a result of irrigation, with consideration of the available assimilative capacity. For the purpose of this study, the available assimilative capacity is determined in a manner consistent with the SWRCB Recycled Water Policy by comparing current groundwater quality with applicable water quality standards, and calculating 20% of the difference between those two values. For constituents where the current groundwater concentration exceeds the water quality standard, there is zero available assimilative capacity for that constituent.

Groundwater degradation potential was determined for the entire study area on a scale of 1 to 100, with 1 representing ideal locations for irrigation with recycled water with regard to groundwater protection based on the area's physical characteristics and the quality of the local recycled water source. The maximum score of 100 represents the least ideal conditions for recycled water irrigation.

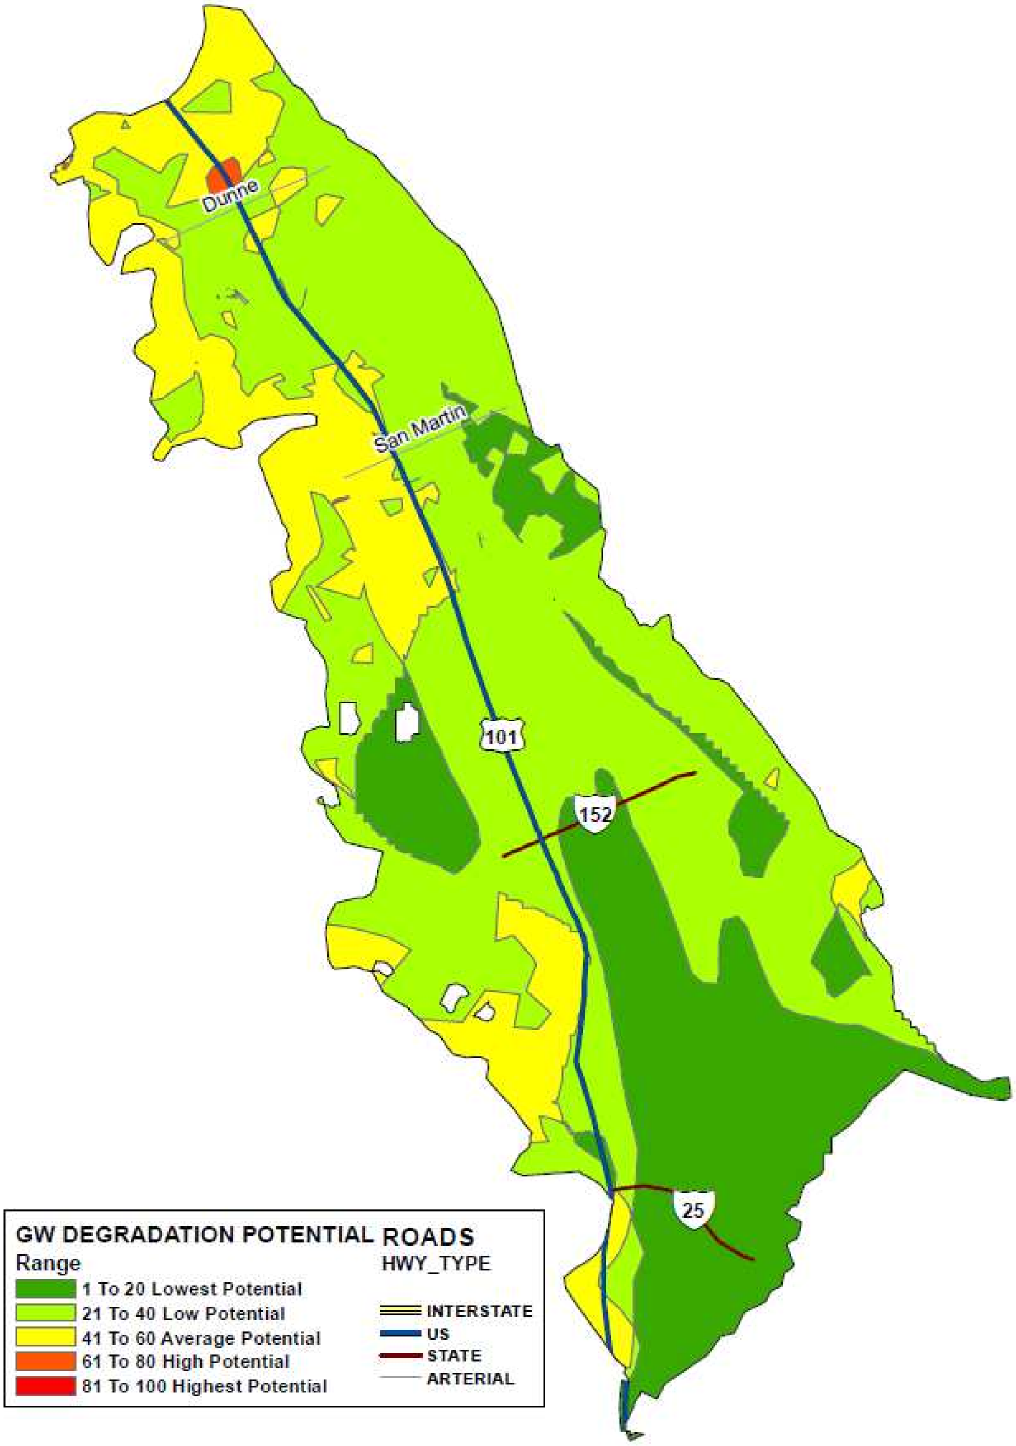
The groundwater degradation potential in the Santa Clara Subbasin is largely of lowest to average potential with a few areas regarded as high or highest. The rating in the Santa Clara Subbasin ranges from 8 to 96. Groundwater degradation potential in the Llagas Subbasin is largely of lowest to average potential and with a few areas regarded as high. The evaluation did not find any areas of the highest groundwater degradation potential in the Llagas Subbasin. In the Llagas Subbasin, the groundwater degradation potential rating ranges from 11 to 70. Comparatively, the Santa Clara and Llagas Subbasins share a similar distribution in groundwater degradation potential with a majority of lowest and low potential found in the confined areas and more average potential in the unconfined areas. Groundwater degradation potential was found to be generally low in the confined areas. Groundwater degradation potential in the unconfined areas was found to be generally average with some areas regarded as high or highest.

The distribution of the relative rating for groundwater degradation potential for the Santa Clara and Llagas Groundwater Subbasins is shown below.

Groundwater Degradation Potential for the Santa Clara Groundwater Subbasin:



Groundwater Degradation Potential for the Llagas Groundwater Subbasin:



2.4. Proposed Recycled Water Irrigation Screening Levels

Proposed recycled water irrigation screening levels (PRWISLs) are developed for irrigation, in conjunction with best management practices (BMPs) and ongoing monitoring recommendations, to protect groundwater quality. PRWISLs are based on the soil aquifer treatment capacity of a given area, the representative groundwater quality, and the constituent's potential threat level.

The PRWISL is defined as the maximum concentration of a recycled water constituent for irrigation at which minimal groundwater degradation potential can be achieved. The PRWISL of a given constituent is developed by assuming that the other recycled water constituents are equal to or less than the representative groundwater quality. The PRWISL of a single constituent represents the maximum tolerable concentration at which the target groundwater degradation potential can no longer be achieved independent of what the other constituent concentrations are. PRWISLs are advisory levels based on the findings from this study and may be used to help guide the use and expansion of recycled water. The inputs to the PRWISLs calculations are dependent on current groundwater quality and soil aquifer treatment capacity. Therefore, the applicable PRWISL varies depending on these two factors. Tables of PRWISLs for Santa Clara and Llagas Groundwater Subbasins are shown below.

If adequate site-specific information is available, the soil aquifer treatment capacity, groundwater degradation potential, and proposed recycled water irrigation screening levels can also be calculated directly.

2.5. Best Management Practices

Best management practices (BMPs) are recommendations to maintain optimal use of recycled water for irrigation while protecting groundwater. BMPs evaluated in this report are specific to recycled water use as an irrigation source for landscape with the goal of minimizing degradation of groundwater resources. BMPs to help protect groundwater quality include:

- Improve Recycled Water Quality: Dilution with higher quality water (such as potable or advance treated water) may be an appropriate measure for areas where the quality of the recycled water is above proposed recycled water irrigation screening levels. In addition, source control such as modification to the treatment processes or investigation and elimination of constituent sources from the waste stream may be options for improving recycled water quality.
- Fertilizer Application: Reduced fertilizer application can minimize potential impacts of migration of nutrients found in recycled water to groundwater.
- Site Selection: Careful selection of sites for recycled water application, through use of soil aquifer treatment capacity, and other methods, is important for avoiding areas that have poor hydrogeological conditions for recycled water application and avoiding the mobilization of other contamination sources that may be present onsite.
- Irrigation Optimization: Optimizing the irrigation system minimizes the total volume of irrigation needed for application and consequently minimizes the mass loading of recycled water constituents.
- Salt and Nutrient Management Plan: The purpose of a salt and nutrient management plan is to protect groundwater from accumulating concentrations of salts and nutrients that would degrade the quality of groundwater and limit its beneficial uses.
- Gypsum Application: Gypsum application can promote soil drainage which is important in preventing water logging and possible runoff of recycled water to surface waters, but also accelerates migration of recycled water constituents to groundwater. Therefore, its use needs to be carefully balanced.

2.6. Ongoing Monitoring Recommendations

Recommendations for ongoing monitoring were developed to monitor the potential long term impacts to groundwater from use of recycled water for irrigation in the Santa Clara and Llagas Subbasins. The goal of the ongoing monitoring is to provide timely recognition of any adverse changes in groundwater quality due to application of recycled water. This monitoring schedule serves as a general guideline for monitoring activities. Future modifications to this monitoring approach may be appropriate to optimize this program.

Site-specific data can be used to directly calculate the groundwater degradation potential to help determine if additional monitoring is needed. The use of this data, along with available groundwater monitoring results from areas with similar physical and recycled water quality characteristics may reduce the need for additional monitoring.

The following is a summary of proposed criteria for achieving adequate monitoring:

1) Select or install wells at or adjacent to sites where recycled water irrigation is implemented. Monitoring wells should be downgradient of the application area.

2) While not every irrigation site needs to be monitored, at least one should be monitored to represent each region of expansion with similar calculated GWDP values. If a region of expansion contains different rating categories of GWDP, consider monitoring an irrigation site in each unique subregion.

3) Monitoring wells between application areas and production wells will be useful in monitoring water quality that may affect production.

4) Monitor for the groundwater of interest (i.e. in the principal aquifer) and in shallower aquifers. Shallower aquifers can provide an early indication of changes in water quality.

5) Avoid monitoring wells that are screened in multiple aquifers, since samples would effectively be an average groundwater concentration across multiple aquifers.

6) Use denser monitoring well spacing in areas of higher GWDP where groundwater degradation is most likely to occur.

Below is a recommended schedule of groundwater sampling, with the year indicating the amount of time after recycled water application begins:

Highest Groundwater Degradation Potential in Represented Area	Monitoring Frequency		
	Year 1	Year 2-4	Year 5 and beyond
1-20	Quarterly	Semi-annually in spring and fall	Annually in fall
21-40	Quarterly	Quarterly	Semi-annually in spring and fall
41-60	Monthly	Quarterly	Semi-annually in spring and fall
61-100	Monthly	Quarterly	Quarterly

After a period of monitoring events, if evaluation of the data obtained demonstrates that the quality of groundwater has not degraded past 20 percent of the assimilative capacity and does not show an increasing trend, consideration may be given to reducing the groundwater monitoring scope by decreasing the monitoring frequency or the number of wells monitored. Reduced groundwater monitoring scope should still be within reason to adequately ensure groundwater quality is maintained. Before a reduction in monitoring scope, trend analysis with forward projection of the groundwater concentrations should be used to demonstrate that the concentrations will not exceed 20 percent of the assimilative capacity over a longer time frame. Conversely, if adverse impacts are encountered in a specific area the monitoring scope can be adjusted to increase in frequency or in the number of wells monitored in the specific area.

Recycled water monitoring is recommended for wastewater treatment plants in order to verify that recycled water quality does not change over time. If recycled water quality worsens over time, additional measures, such as dilution or source control as specified in BMPs should to be implemented in order to maintain the same level of groundwater protection. At minimum, annual monitoring of recycled water is recommended from each wastewater treatment plant that provides recycled water for irrigation use. More frequent monitoring of recycled water may be useful for determining seasonal changes in the water quality, or evaluating water quality changes when improvements in the treatment process are implemented. During the pilot study, as discussed in Volume III, constituent concentrations in recycled water were observed to vary within the distribution system. Therefore, it is recommended that samples are collected at various points in the distribution system to evaluate the quality of recycled water being applied for irrigation. Samples should be collected at the irrigation site closest to the recycled water source, and at the irrigation site furthest from the recycled water source.

2.7. Further Study

The conclusions made in this report are supported with the findings from the evaluations conducted in this study using the best professional judgment. Further monitoring and additional site-specific data can strengthen and refine the findings of this report. Further monitoring of recycled water constituents, particularly the emerging contaminants for which limited data are currently available, will increase sample size, which could be used to more accurately evaluate concerns such as groundwater degradation potential. Groundwater monitoring is ongoing at the pilot study site, and those results should be considered along with the findings of this study. Additional studies, such the ongoing monitoring of the recycled water irrigation at the pilot study site, pilot testing of areas within the study area with hydrogeological settings different from those found in at the IDT site, could also help verify and/or update the findings of this study. Additional study of recycled water in the deeper zones may be appropriate where impacts have occurred in the shallow zones.

VOLUME I
LITERATURE REVIEW AND DATA ANALYSIS
RECYCLED WATER STUDY

1. INTRODUCTION

This report presents the results of a study to evaluate the impacts of recycled water on groundwater resources in the Santa Clara and Llagas Groundwater Subbasins in Santa Clara County. The study was completed by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD). This study used a combination of approaches, including literature review, data analysis, fate and transport evaluations, and a full pilot study at a site in the Santa Clara Groundwater Subbasin. Volume I includes the first of these approaches, the literature review and the data analysis, which includes 1) available data from related studies that can be used for this project, 2) relevant hydrogeological data, 3) methodologies proposed for assessing impact to groundwater from recycled water, 4) available geochemistry of recycled water, including a prioritized list of chemicals of concern.

1.1. Purpose

Volume I covers two major components of this study: literature review and data analysis. The purpose of the literature review is to collect and summarize relevant recycled water studies in Santa Clara County, including studies previously conducted by the SCVWD. In addition, literature related to recycled water and relevant studies were reviewed. The goals for the literature review were identified as the following:

- Determine the range of characteristics of recycled water found in recycled water from the four producers (common chemical and biological constituents that should be evaluated in this study);
- Investigate the effects of soil permeability from recycled water;

- Review conclusions of previous relevant studies, and determine areas that require further investigation (i.e. chemicals that lack information in terms of fate and transport); and
- Identify investigative techniques (e.g. modeling tools) that could be used for the remainder of the study.

Part of determining the range of characteristics of recycled water involves a data analysis. The purpose of the data analysis is to review available data related to hydrogeology, recycled water, and groundwater quality. The data will be used to observe the fate and transport of identified chemicals of concern. The data analysis evaluated the overall quality of recycled water using data from the four producers (i.e. PARQWCP, SWPCP, SJ/SC WPCP and SCRWA) which have varying recycled water qualities. Similarly, the data analysis evaluated the overall quality of groundwater using data from the two subbasins (ie Santa Clara and Llagas) which have varying groundwater qualities. The following goals were identified for the data analysis:

- Identify which constituents have been detected in recycled water sources;
- Determine the frequency of detection of each constituent in recycled water;
- Determine the maximum, minimum, and representative concentration of each constituent in recycled water;
- If available, compare recycled water constituent concentrations with available groundwater chemistry data from the Santa Clara and Llagas Groundwater Subbasins, and evaluate the overall difference in water quality; and
- Identify constituents which may or may not have the potential to impact groundwater quality based on significantly higher overall concentrations.

1.2. Volume I Organization

During the course of the literature review, three overall subjects were found to be prevalent in previous studies of recycled water application for irrigation. This volume of the report is subdivided into these three subjects. The first subject is the origin, fate, and transport of chemical and biological constituents commonly found in recycled water. To consolidate the available information for each constituent, the results of the data analysis are discussed in Section 2 of this volume along with the literature review information for each constituent. The second subject is a general evaluation of the potential for soil plugging that can occur when using recycled water for irrigation. The final subject is the evaluation and use of modeling tools for predicting the fate and transport of chemicals through the unsaturated vadose zone. These subjects are addressed in Sections 3 and 4, respectively, of this volume of the report.

1.3. Approach

Resources for the literature review were identified through SCVWD as well as other experts in the field of recycled water application. Based on previous relevant SCVWD reports and the advice of an expert panel, Locus prepared a list of key topics for locating references. The topics were used with online resources such as the U.S. Salinity Laboratory (*http://www.ars.usda.gov/main/main.htm*), and conventional sources including local university libraries. Using this approach, Locus maximized use of available resources to address the goals of this study. The literature review was conducted in 2007 at the beginning of this study. However, the review does include updates using selected literature as current as 2009 as part of the review process for this document.

For the data analysis, the ranges of concentrations for each constituent were compared between populations of recycled water from the four local sources and groundwater samples from the Santa Clara and Llagas Groundwater Subbasins. SCVWD provided available chemistry data for groundwater and recycled water samples in electronic and hard copy laboratory reports. The results were compiled into histograms or box plots depending on the amount of data available and plotted for comparison.

To prioritize the chemicals in recycled water, categories were developed to distinguish chemicals that may have a greater potential to impact groundwater than others. The categories were developed based on the available fate and transport information for the constituents in recycled water and the available data analyses.

2. CONSTITUENTS OF RECYCLED WATER

Recycled water commonly contains a number of unique chemical and biological constituents introduced through the original use of the water, or through the treatment processes that the water undergoes after use. One major goal of this study is to determine whether any of these constituents have the potential to negatively impact groundwater if recycled water is used for irrigation. In this section, each of these constituents is discussed, either individually or as a group of related constituents as appropriate.

2.1. Methodologies

The data analysis for each constituent includes a comparison between recycled water and groundwater quality data. The methods used to make this comparison are discussed below.

2.1.1. Data Sources

For the data analysis, SCVWD provided available water quality data for historic groundwater and recycled water samples. Historic groundwater data includes data from the SCVWD database, including data from the City of San Jose's Groundwater Monitoring and Mitigation Program (GMMP), which has sampled from numerous monitoring wells in the Santa Clara County. The date range of the historic groundwater data is from 1973 to 2007, and includes data from the shallow and deep aquifers. Both shallow and deep groundwater were included to adequately represent groundwater concentrations. Recycled water data used in the evaluation ranged from 2001 to 2007. The data were not reviewed for quality assurance/quality control (QA/QC) as part of this project and are assumed to have met the SCVWD quality assurance and quality control requirements.

Many data were available in electronic form, but some, particularly the recycled water analyses, were only available in hard copy laboratory reports. In order to adequately represent every constituent of recycled water, some manual data entry was required for the statistical analysis. First, the laboratory reports were reviewed to identify each constituent that had been detected in at least one of the recycled water samples.

The laboratory reports included many analyses, but there were many analytes that were not detected in any samples. To minimize the manual data entry, constituents that were not detected in any recycled water samples were not tabulated. A complete list of all chemicals that were analyzed in the recycled water from the SCVWD database is presented in Table I-2-1. Results for each parameter that was detected in at least one of the recycled water samples are presented in Table I-2-2.

SCVWD maintains a large database of groundwater quality information, which was used to identify the representative characteristics of groundwater in the Santa Clara and Llagas Groundwater Subbasins. Some of the hard copy laboratory reports provided by SCVWD included groundwater samples that were not entered in the database. However, for most of the analytes in the laboratory reports, the existing SCVWD database already includes a large amount of groundwater quality data. Many of the monitoring parameters have thousands of records in the database. Therefore, the additional benefit of manually adding the approximately twenty samples from the laboratory reports was minimal. Data for constituents found in the laboratory reports but not in the SCVWD database were manually entered so that some representation of groundwater quality could be obtained.

2.1.2. Data Analysis

Once the available chemistry data for groundwater and recycled water were compiled, exploratory statistical analyses were applied to the data. Using the SCVWD groundwater quality database, histograms were prepared for each constituent detected in recycled water. For this analysis, concentration values below detection were considered zero values. This simplification of the data set was necessary to avoid skewing the histograms, since there is a significant amount of variability in the reporting limits in the database. The use of the reporting limit or half the reporting limit is common in statistical analyses of this type, but for this analysis it would show false variability for nondetect values. Another simplification used for this study was to consider all available concentration data equally. That is, no consolidation was made for multiple samples collected from the same well or at the same time. However, given the large data count for the groundwater samples, the potential error caused by this simplification is minimal.

Groundwater chemistry histograms are shown in Appendix I-A. For many constituents, the histograms provide a good representation of the range of concentrations in groundwater. The histograms are scaled so that the majority of the data are visible on the plot. Some data outliers may not be represented, but the scale presents the best resolution for most of the data. The histograms are less useful for some constituents that are infrequently detected in groundwater, where almost all of the data are plotted as zero values. For these constituents, it is useful to review the summary statistics included on each histogram. Summary statistics calculated for each constituent include the minimum, maximum, median, mean, count, and frequency of detection are provided in figures found in the appendices and within the text of Section 2.

Recycled water chemistry data are also presented on each of the groundwater histograms in Appendix I-A. Due to the small number of recycled water samples available for this study, a full histogram of the data does not return useful results. However there were a sufficient number of samples to prepare simplified box plots of the data, showing the minimum, maximum, and median concentrations. For these box plots, the median was selected as the most representative concentration as opposed to the mean, since it is not impacted by outliers in the data set. However, the mean and other summary statistics for recycled water are also presented on the histogram for comparison.

Appendix I-B includes box plots for additional constituents where there was insufficient data (less than 40 data values) to prepare a histogram. These constituents are not commonly monitored in groundwater, therefore there is a limited amount of data for them. However, some groundwater samples collected as part of the SCVWD Advanced Recycled Water Treatment (ARWT) Feasibility Project were analyzed for these constituents, and there is a sufficient number of results to perform the comparison.

During the data analysis, three recycled water constituents were identified for which there were no corresponding groundwater analyses. These constituents are presented with only recycled water data in Appendix I-C.

2.1.3. Parameter Categorization

Constituents are prioritized based on their potential to negatively impact the beneficial uses of groundwater. A beneficial use includes municipal, domestic, industrial, and irrigation. Five categories were developed to classify constituents. The classification of these constituents is based on the current available knowledge of fate and transport characteristics and on the results from the data analysis. The five categories are:

A) Significant Potential for Impact. The fate and transport characteristics and data analysis suggest that the constituent may negatively impact ground water.

B) Important Parameter. Although this constituent may not directly impact groundwater, it is useful to monitor because it can influence other constituents.

C) Inconclusive. Different studies concerning the same constituent present conflicting information on fate and transport characteristics or based on the constituent's characteristics, it is still unknown how groundwater may be impacted.

D) Minimal Potential for Impact. Groundwater is not likely to be impacted because 1) the fate and transport characteristics suggest that the constituent has a high affinity for attenuation and/or 2) the concentration in recycled water is less than or similar to the concentration found in groundwater or less than water quality standards. Therefore, recycled water cannot impact the constituent concentrations in groundwater.

E) Insufficient Information. There is not enough information concerning the fate and transport of the constituent to evaluate the potential impacts to groundwater.

The assigned categories for each of the evaluated constituents were used as a guide for to develop monitoring plans for the bench test and pilot study, which are described in Volumes II and III, respectively .

2.2. General Water Quality

General water quality parameters are typically inexpensive to monitor. Many of these parameters can be easily monitored in the field, and can provide an overall indication of water quality. In addition, these parameters provide critical information about the chemistry of the water and how constituents may react with the environment when applied as irrigation water. Many of the parameters discussed below are reactive either with soil, in-situ waters, and/or plants depending on the water chemistry. Therefore, the general water chemistry provides a basis for understanding the potential fate and transport of recycled water constituents through the vadose zone to groundwater even if the parameters themselves do not represent potential constituents of concern to groundwater.

2.2.1. pH and Alkalinity

The ARWT Feasibility Project reported that pH from surface water, groundwater, and recycled water were found to be near neutral (SCVWD, 2004). The data analysis performed for this project confirms this conclusion, as shown in the histogram in Appendix I-A. The median pH value is slightly lower for recycled water, but the range of pH values for recycled water is still within the range for the majority of groundwater values.

One study in Florida using recycled water for irrigation of several golf courses found that the pH of recycled water ranged from 5.3 to 8.7, which was similar but more variable than the pH of the local groundwater. The study also found that the pH was lower in groundwater at golf courses irrigated with recycled water compared to those irrigated with local well water, although the mechanism for that difference was not determined (United States Geological Survey [USGS], 1996). As with any irrigation water, the pH of recycled water used for irrigation may change during exposure to the environment through reactions between the dissolved constituents and the environment. Direct comparison of recycled water pH and groundwater pH may not be an accurate method of evaluating the potential effects, although establishing pH is important for understanding the fate and transport of other recycled water constituents.

Another potential issue associated with the pH of water used for irrigation is the potential for additional solubilization of metals. The amount of metals that can be leached from soil is highly dependent on the pH of the infiltrating water. Lower pH values have the potential to mobilize metals out of the soil. However, the median pH observed in recycled water samples from the data analysis is 7.4, which is above neutral. Therefore, infiltration of recycled water with this pH is not expected to have a significant effect on the mobilization of metals.

Alkalinity is the measure of the ability of water to neutralize acids, caused by the presence of hydroxide, carbonate, and bicarbonate anions. High alkalinity indicates a resistance to changes in pH. In a Florida study using recycled water for irrigation of several golf courses, alkalinity was found to be lower in groundwater at golf courses irrigated with recycled water compared to those irrigated with local well water (USGS, 1996).

Recycled water samples included in the data analysis showed pH values ranging from 6.5 to 8.1, with a median value of 7.4. The groundwater samples tend to be slightly more basic, with a median of 7.7. The total alkalinity and bicarbonate alkalinity values for recycled water samples are similar to the groundwater samples. Since both pH and alkalinity values are similar for recycled water and groundwater, there is very little potential for recycled water application to affect the pH of groundwater. However, these parameters are ranked as category B) Important Parameters because they are useful parameters influencing the fate and transport of metals.

Summary Data for pH (pH units), Category B

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	6.5	7.4	7.300	8.1	25	100%
Groundwater	0	7.68	8.66	832	8729	100%

Summary Data for Alkalinity (Total) As CaCO3 (mg/l), Category B

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	65	172	171	263	22	100%
Groundwater	1.9	219	237	5500	5549	100%

Summary Data for Bicarbonate Alkalinity (mg/l), Category B

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	77	191	188	320	29	100%
Groundwater	0	227	258	1600	1802	100%

2.2.2. Hardness

Hardness measurements represent the presence of polyvalent cations (typically calcium and magnesium) in water. The hardness of recycled water is not expected to have any impact on groundwater quality, since the range of hardness in recycled water is within the majority of hardness values for groundwater. All of the recycled water sample results fall within a relatively narrow range of values (180 to 319 milligrams per liter (mg/L) as $CaCO_3$). Hardness in groundwater samples ranges from 0 to 2150 mg/L as $CaCO_3$. Hardness is ranked in category D) Minimal Potential for Impact, because the concentrations in recycled water and groundwater are similar.

Summary Data for Hardness (Total) As CaCO3 (mg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	180	245	243.150	319	20	100%
Groundwater	0	250	267	2150	5986	99.9%

2.2.3. Turbidity

Turbidity is the measure of the light-transmitting properties of water, which primarily represents the presence of suspended and colloidal material. Since pathogens can be attached to these particles, higher turbidity values can be correlated to higher levels of pathogens. Previous studies have shown some impact to groundwater turbidity caused by recharge from a low-quality water source. However, the results appeared to be temporary, and groundwater turbidity returned to normal after recharge from the water source ceased (Pitt et al., 1996).

The USEPA drinking water standard for turbidity is one nephelometric turbidity unit (NTU). Although the representative turbidity values for recycled water are higher than those for groundwater, median turbidity values for both groundwater and recycled water are below the USEPA drinking water standard, as shown in Appendix I-B. However, turbidity is typically higher in surface water than groundwater and the process of infiltration through soil typically changes the turbidity of infiltrating water depending on the depth to groundwater, soil characteristics, and the rate of inflow. In addition, while the turbidity of groundwater is often controlled by the hydrogeology of the aquifer, the measured turbidity of groundwater samples is highly affected by well construction and sampling procedures. Because turbidity in recycled water is similar to groundwater in mean concentrations, it is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Turbidity (NTU), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0.19	0.7	0.804	2.2	18	100%
Groundwater	0	0.15	0.780	120	3775	86.4%

2.2.4. Total Dissolved and Suspended Solids

Total dissolved solids (TDS) and total suspended solids (TSS) are parameters of concern because of the potential adverse impacts on the permeability of the soil (see Section 3). High TDS levels can also retard the growth of vegetation and at extremely high levels, can affect the potability of water. SCVWD's ARWT Feasibility Project technical memo reported that use of recycled water for irrigation will most likely cause TDS levels in groundwater to rise under long term conditions for an unconfined aquifer (SCVWD, 2004). A recycled water irrigation study in Hawaii compared irrigated recycled water to pore water collected at a 5 foot depth, and found that dissolved salts were not removed by the soil filtration process. Dissolved salts were regarded as posing the largest impact from recycled water used for irrigation (Brown and Caldwell, 2005).

TDS is reported in Appendix I-B as Total Filterable Residue. Concentrations of TDS in recycled water range from 630 to 1000 mg/L, consistently higher than concentrations in groundwater. USEPA has set a secondary drinking water standard for TDS of 500 mg/L. TDS is ranked in category A) Significant Potential for Impact, and should be included for monitoring in the study in the study. TSS is also reported in Appendix I-B. The range, detection frequency, and representative values for TSS are all similar for groundwater and recycled water. TSS is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring.

Summary Data for Total Filterable Residue at 180C (Total Dissolved Solids) (mg/l), Category A						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	630	724.5	752.100	1000	20	100%
Groundwater	0	384.5	456.59	12180*	3872	100%

Note: *TDS value from well located next to San Francisco Bay, sampled once in 1972.

Summary Data for Total Suspended Solids (mg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	2.167	10	18	44%
Groundwater	0	0	3.737	10	19	42%

2.2.5. Dissolved and Total Organic Carbon

Total organic carbon (TOC) poses a concern to groundwater because TOC can react with disinfectants to form disinfection by-products. Previous studies have found that that TOC and dissolved organic carbon (DOC) concentrations in recycled water are generally higher than corresponding concentrations in drinking water derived from the same source (American Water Works Association [AWWA], 2001). TOC concentrations in recycled water for groundwater recharge projects are regulated by the California Department of Public Health (DPH) according to Draft DPH Groundwater Recharge Reuse Regulations (SCVWD, 2004).

The ARWT Feasibility Project ranks TOC to have "insignificant" to "slight" potential impact on groundwater in the unconfined portion of the Santa Clara Subbasin, depending on the type of irrigation (agricultural or landscape). TOC is expected to have a minimal potential impact because the mass quantity of TOC added is relatively low and there are known soil attenuation factors. TOC can be attenuated in the environment through adsorption and biodegradation. However, in the unconfined portion of the Llagas Subbasin, the ARWT project ranked TOC to have "slight" to "moderate" potential impact due to the larger quantity of water applied and shallower depth to the unconfined zone (5 -15 feet). Due to parts of the Llagas Subbasin which have shallower groundwater, the ARWT Feasibility Project recommended monitoring of this parameter.

A case study by the Los Angeles County Sanitation District (LACSD) where groundwater recharge was applied to a basin through surface spreading found that most TOC was removed in the top several inches of the recharge basin. Hence, TOC concentration was found to not be a function of depth. Another study looking at DOC at the Sweetwater Recharge Facility in Tucson, Arizona found that DOC was reduced from concentrations of 12 to 25 mg/L at the surface to 2 to 3 mg/L at a depth of 125 feet below ground surface (bgs). The Arizona study also found that the concentrations at 125 ft bgs were largely independent of the initial DOC concentration at the surface (AWWA, 2001).

Concentrations of TOC in groundwater ranged from below detection to 0.69 mg/L in the samples included in the data analysis (Appendix I-B). Recycled water concentrations of TOC ranged from 3.99 to 9.62 mg/L, indicating a significant difference. Measurements of UV-254, which are typically correlated directly to TOC concentrations, show a similar distribution. DOC concentrations in recycled water sources ranged from 5 to 9 mg/L. Because of potential impacts particularly to the shallowest zones in the study area, TOC and DOC are ranked in category A) Significant Potential for Impact, and should be included for monitoring in the study.

Summary Data for Dissolved Organic Carbon (mg/l), Category A						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	5	6.3	6.560	9	5	100%
Groundwater	NA	NA	NA	NA	NA	NA

Summary Data for Total Organic Carbon (mg/l), Category A						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	3.99	6.595	6.630	9.62	18	100%
Groundwater	0	0.31	0.319	0.69	19	79%

2.2.6. Redox Potential and Dissolved Oxygen

The oxygenation state of water either measured as oxidation reduction potential (ORP) or represented by dissolved oxygen is an important physio-chemical parameter of water which affects the chemical state and therefore the fate and transport of many organic and inorganic constituents of recycled water. Because it is a very reactive condition, differences between the oxidation state of recycled water and groundwater do not in and of themselves present a potential impact. However, the oxidation state and the redox potential of the recycled water and soil present an important parameter affecting the fate and transport of constituents which are mobile or immobilized based on oxidation state.

Recycled water can theoretically alter the redox conditions of groundwater if the biological oxygen demand (BOD) of the recycled water is very high and persists during transport to groundwater. During interaction with soil, oxygen in the water is consumed as organic material is degraded (oxidized), and the redox potential becomes more negative. If the water already contains a high BOD, then the recycled water could presumably continue to scavenge oxygen or oxidants from soil and groundwater after it reaches the water table, thereby lowering the oxidation state of groundwater. Because mechanisms for oxygen transport into the saturated zone are minor, oxygen depletion can occur creating an anoxic plume of recharged water that may affect the aquifer.

This effect was observed in a case study of groundwater recharge through surface spreading of recycled water by the LACSD, where oxygen levels in the groundwater were found to be below saturation. However, the oxygen content remained above zero at the site (SCVWD, 2004). Although generally not a concern in the US, anoxic aquifers have occurred elsewhere in the world (Metcalf and Eddy, 2007).

Low redox potential in recycled water remains an indirect concern for groundwater, by reducing iron, manganese, and arsenic compounds in soils to soluble forms. Distribution of recycled water through spray irrigation systems may alleviate this concern by aerating the water prior to infiltration into the soil. Therefore the type of irrigation system may be a significant factor in determining the potential impact of low redox potential in recycled water. A data analysis for redox potential has not been prepared, since the effect of redox potential is a result of complex interactions between recycled water, soil, and in-situ waters and concentrations of oxidants and reactants and is not necessarily a direct result of the redox potential of recycled water. DO and ORP are ranked category B) Important Parameters, and should be included for monitoring in this study.

2.2.7. *Silica*

Silica concentrations in recycled water tend to be lower than those in groundwater (Appendix I-B). This is expected, since groundwater is in constant contact with silica-bearing sediments. Dissolved silica concentrations are typically temperature and pH controlled. Silica is not known to cause any adverse health effects in water, but it can cause scaling problems in industrial systems and groundwater wells. Since the observed concentrations of silica in recycled water sources are lower than those in groundwater, recycled water has very little potential to impact silica in groundwater. Hence, silica is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Silica (mg/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0.9	15.8	18.700	34.6	18	100%
Groundwater	0	25	25.6	244	4416	99.5%

2.3. Cations and Anions

Recycled water may contain several metals and other ions that include aluminum, boron, cadmium, calcium, chloride, copper, cyanide, fluoride, iron, lead, magnesium, manganese, nickel, sodium, sulfate, and zinc. The percentage of each of these constituents remaining after tertiary treatment will depend on the specific treatment train used.

2.3.1. *Transition and Post-Transition Metals*

Recycled water and groundwater samples have been analyzed for a group of metal ions. The group of transition and post-transition metals includes most of the metallic ions commonly dissolved in water, including aluminum, cadmium, copper, iron, lead, manganese, nickel, and zinc. Many of these metals do not warrant a full evaluation because concentrations in recycled water are similar to groundwater, and therefore pose little potential for groundwater impact. In the data analysis, concentrations of aluminum, manganese, and zinc were found to have similar distributions in recycled water and groundwater samples. Therefore, these metals are ranked in category D) Minimal Potential for Impact, and are not recommended for monitoring in the study. A few of the other metals detected in recycled water samples are discussed below.

Summary Data for Aluminum (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	39.6	174	18	33%
Groundwater	0	0	29.8	3800	1955	24%

Summary Data for Manganese (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	13.137	35	19	42%
Groundwater	0	0	28.4	1620	3830	36.8%

Summary Data for Zinc (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	32.263	130	19	42%
Groundwater	0	0	20.7	9400	3268	28.3%

2.3.1.1. Iron

Iron is ubiquitous in soil but is relatively insoluble in water except under reducing conditions. Iron concentrations in recycled water samples were generally lower and less frequently detected than in groundwater samples which probably reflects differences in redox conditions. Although there is no Maximum Contaminant Level (MCL) for iron, a secondary drinking water standard which is recommended but not enforced by USEPA is 300 micrograms per liter (µg/L). The maximum concentration observed in recycled water samples included in the data analysis was 120 µg/L. Iron is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Iron (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	6.700	120	18	6%
Groundwater	0	10	102	26000	4600	52.4%

2.3.1.2. Lead

Lead adsorbs strongly to soils, hence it does not typically migrate to groundwater from surface applications such as irrigation. The drinking water action level for lead is 15 µg/L (USEPA, 2003). In the data analysis, lead was detected in one of the 19 recycled water samples, at a concentration of 11 µg/L.

Detections of lead in groundwater are more frequent, and have shown higher concentrations. Therefore, lead concentrations in groundwater are not likely to be affected by recycled water use. Hence, lead is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Lead (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.579	11	19	5%
Groundwater	0	0	0.892	50	2556	12.4%

2.3.1.3. Nickel

Nickel is one of the most mobile metals. Nickel concentrations in groundwater are controlled by the partitioning between water and soil which is controlled by adsorption/desorption and precipitation/dissolution processes. Adsorption/desorption is dominant in soil with low pH. When pH is high or if nickel concentrations are high, precipitation/dissolution processes control the partitioning of nickel between water and soil. Nickel adsorption is dependent on the soil's cation exchange capacity, pH, texture, carbonate content, organic matter, sesquioxides, and chelating agents. Organic matter, layer silicates, hydrous oxides of silicon, aluminum, iron, and manganese, and carbonates are important adsorbents in soils (Selim and Iskandar, 1999). Groundwater in the Santa Clara and Llagas Subbasins may have elevated concentrations of nickel due to contact with serpentine bedrock. In the data analysis prepared for this study, nickel concentrations were found to have a similar distribution in recycled water samples and groundwater samples. Therefore, nickel concentrations in groundwater are not likely to be affected by recycled water use. Nickel is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study. USEPA does not currently enforce a drinking water standard for nickel.

Summary Data for Nickel (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	3.105	47	19	11%
Groundwater	0	0	1.67	79	1648	14.9%

2.3.1.4. Cadmium

All compounds of cadmium are hazardous to both plants and animals. Accumulation of cadmium in the kidneys can lead to kidney dysfunction and it is a recognized carcinogen. The federal and state MCL is 5 µg/L for cadmium in drinking water (USEPA, 2003; State of California, 2007). Sorption/desorption, ion exchange and precipitation/dissolution are processes that affect the fate of cadmium. Cadmium interacts with soil through ion adsorption at surface sites, ion exchange with clay material, binding by organically coated particulate matter or organic colloidal material, or adsorption of metal ligand complexes. pH and ionic strength of the soil solution influence sorption of cadmium. Increasing the ionic strength in the soil solution tends to lower the sorption of cadmium. Sorption of cadmium increases as pH increases especially in the pH range from 5.5 to 6.5 where an adsorption edge occurs. Cadmium sorption will decrease in the presence of metals and cations competing for sorption sites (Selim and Iskandar, 1999).

Cadmium was detected in one of the recycled water samples included in the data analysis, from SJ/SC WPCP with a concentration of 12 µg/L. Higher concentrations have been observed in groundwater, although the relative detection frequency for groundwater is lower. Because cadmium is not detected in recycled water frequently, it is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Cadmium (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.632	12	19	5%
Groundwater	0	0	0.0841	21	2518	3.8%

2.3.1.5. Copper

Copper is a metal that is both essential to life and toxic at high or sustained concentrations. Copper retention in soil is intricate. Copper (II) can complex with a number of anions that are commonly found in natural water. At low copper concentrations such as those typically found in environmental samples (<32,000 µg/L), the presence of tartaric acid and fluvic acid decreases retention in soils. Tartaric acid is commonly introduced in the environment through plant roots and decomposing plant material. Observed increases in copper mobility have been related to binding with DOC (Selim and Iskandar, 1999).

USEPA has set a drinking water action level for copper of 1,300 µg/L, based on reducing the corrosiveness of drinking water (USEPA, 2003). Copper was detected in only one of the recycled water samples with a concentration of 61 µg/L. Concentrations of copper in groundwater are generally higher, and are detected more frequently. Therefore, it is unlikely that copper concentrations in groundwater will be significantly affected by use of recycled water. Hence, copper is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Copper (µg/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	3.211	61	19	5%
Groundwater	0	0	6.15	2000	3058	17.5%

2.3.2. Other Ions

Recycled water commonly contains several other metallic and non-metallic ions of natural and anthropogenic origin.

2.3.2.1. Boron

Boron compounds are used in a wide range of industrial applications that eventually find their way into the water supply. In the environment, boric acid and borate ions are the most frequent form of boron. Boron has been shown to adsorb to soils, depending on the pH of the water. The World Health Organization has established a provisional guideline for boron in drinking water of 500 µg/L (World Health Organization, 1998b). The majority of boron concentrations in recycled water and groundwater samples included in the data analysis were lower than this value, although one sample collected from SJ/SC WPCP showed a concentration of 505 µg/L. Boron concentrations in the recycled water sources analyzed in this study fell within a fairly narrow range. Boron concentrations in groundwater have been observed as high as 5,200 µg/L within the study area. However, the median boron concentration in recycled water samples (416 µg/L) was higher than the median for groundwater samples (134 µg/L). Boron is toxic to some plants at lower concentrations than humans and therefore the use of recycled water for irrigation may be limited by the effects on plants rather than potential impacts to groundwater. Because the degree of boron adsorption to soils is dependent on pH, which may vary, boron is ranked in category C) Inconclusive, and should be included for monitoring in the study.

Summary Data for Boron (µg/l), Category C						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	207	416	398	505	19	100%
Groundwater	0	134	196	5200	1815	85%

2.3.2.2. *Cyanide*

Generally, cyanide is not a persistent or stable constituent in water or soil. It volatilizes quickly and can biodegrade. Cyanide also does not accumulate in aquatic organisms. However, because cyanide does not bind to soils, it may leach to groundwater if it doesn't evaporate (USEPA, 2006b). The USEPA MCL in drinking water for cyanide is 200 µg/L (USEPA, 2003). The California MCL is 150 µg/L (State of California, 2007). Standards for cyanide in surface water bodies are more stringent than drinking water standards. Currently, the the RWQCB specifies a screening level of 1 µg/L for aquatic habitat goal based on California Toxics Rule (California Regional Water Quality Control Board, 2007). Cyanide has been detected in two of the recycled water sources included in the data analysis, SCRWA and SJ/SC WPCP. Both detections were below the California MCL (CA MCL) for drinking water, but above the cyanide aquatic habitat goal. Cyanide is detected infrequently in groundwater but the maximum is higher than the observed maximum in recycled water. Cyanide is ranked in category C) Inconclusive, and should be included for monitoring in the study.

Summary Data for Cyanide (µg/l), Category C						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	4.5	58	14	14%
Groundwater	0	0	0.459	350	1059	0.6%

2.3.2.3. *Fluoride*

Fluoride is added to many drinking water sources as an additive for oral health. Due to fluoridation in the water supply from the San Francisco Public Utility Commission, some communities in Santa Clara County receive fluoridated drinking water. Drinking water for the Gilroy area is not currently fluoridated, but there is a low concentration of natural fluoride in the groundwater source for Gilroy's drinking water. As a result, the recycled water from SCRWA (located in Gilroy) has consistently lower fluoride concentrations (ranging 0.15 to 0.41 mg/L) than the other recycled water sources (ranging 0.55 to 1.69 mg/L). In general, fluoride concentrations in recycled water are higher than those in groundwater. The USEPA MCL drinking water standard for fluoride is 4.0 mg/L. Both the median concentrations for recycled water and groundwater are below the standard. Fluoride adsorbs strongly to soils, and at a low pH, can actually react directly with soil components. However, because fluoride is not harmful to human health or the environment at these concentrations, these effects may not be significant. Because fluoride concentrations in recycled and groundwater are below the drinking water standard, fluoride is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Fluoride (mg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0.15	0.68	0.648	1.69	18	100%
Groundwater	0	0.13	0.518	721	5051	87.3%

2.3.2.4. Calcium, Magnesium, Sodium, Chloride, and Sulfate

Although not generally a health concern, concentrations of calcium, magnesium, sodium, chloride, and sulfate in recycled water have been shown to impact groundwater. USEPA does not currently enforce drinking water standards for these ions, but recommends secondary drinking water standards for chloride and sulfate, both at 250 mg/L. One study in Florida using recycled water for irrigation of several golf courses found that concentrations of calcium were lower in groundwater at golf courses irrigated with recycled water compared to those irrigated with local well water. Sodium concentrations were found to be higher in the groundwater at golf courses irrigated with recycled water than at golf courses irrigated with local well water (USGS, 1996).

High sodium concentrations relative to calcium and magnesium also have the potential to cause clay swelling and affect soil permeability (see Section 3: Soil Aquifer Plugging) but these effects can be partially reversed by salinity. Sodium affects soil when the proportion of sodium relative to calcium plus magnesium is high. When the soil water is highly saline and all constituents including sodium are present in high concentrations, the dispersing effects of sodium are mitigated by high concentrations of magnesium and calcium. When sodium is high and salinity including calcium and magnesium is low, the disruption of the soil can be extensive. Where use of recycled water produces significant increases in sodium, calcium, magnesium, sulfate, or chloride, groundwater salinity and TDS concentrations can also increase producing an adverse effect on water quality.

In the samples reviewed for the data analysis, calcium concentrations in groundwater and recycled water show a similar distribution. The median magnesium concentration was higher in recycled water samples, but the range of concentrations in recycled water was within the range for groundwater. Sodium, chloride, and sulfate concentrations are also higher in the recycled water sources relative to basin groundwater and therefore may affect soil as well as concentrations of these constituents in groundwater. Calcium, magnesium, sodium, chloride, and sulfate are ranked in category A) Significant Potential for Impact, and should be included for monitoring in the study. Special attention needs to be taken with calcium, magnesium, and sodium because of their potential to cause reduced soil permeability.

Summary Data for Calcium (mg/l), Category A

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	40.7	51	51.400	69.2	21	100%
Groundwater	0	56	61.5	916	5813	100.0%

Summary Data for Magnesium (mg/l), Category A

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	26.7	31.7	32.900	42.2	19	100%
Groundwater	0	25	30.7	370	5785	99.9%

Summary Data for Sodium (mg/l), Category A

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	118	148.95	161.600	230	20	100%
Groundwater	0	29	39.7	3570	5798	100.0%

Summary Data for Chloride (mg/l), Category A

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	119	196	207.700	320	20	100%
Groundwater	0	34	61.9	20000	6837	99.7%

Summary Data for Sulfate (mg/l), Category A

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	60.1	96.6	99.800	247	19	100%
Groundwater	0	42.3	54.1	1500	5915	99.8%

2.4. Nutrients

Wastewaters can often contain significant concentrations of organic and inorganic nutrients. Concentrations of these nutrients are also found in recycled water. Some studies have suggested that the presence of these nutrients can provide benefits as a supplemental fertilizer source when used for agricultural irrigation (Toze, 2004). Two of the most common nutrients present in recycled water are phosphate and nitrate.

2.4.1. Phosphate

Generally, phosphorus is a limiting nutrient for plant growth. One of the most common attenuation pathways for phosphate is crop uptake. Past the root uptake zone, phosphate can be attenuated by precipitation. When soluble phosphate is added to acidic soils, the majority of the phosphate turns into iron and aluminum phosphates which are insoluble. In calcareous soils, soluble phosphate forms calcium phosphate (Chang and Chu, 1961). Anaerobic soils have a higher capacity to sorb and release phosphate than aerobic soils. In anaerobic conditions, reduced ferrous compounds have a higher surface area allowing for phosphate to be more readily sorbed or released (Patrick and Khalid, 1974). Sinaj et al. (2002) found that phosphate is highly mobile in the top soil. In the subsoil, phosphate mobility is restricted due to the higher phosphorus-fixing capacity.

Phosphate was detected in every recycled water sample reviewed for this study. The median concentration found in recycled water was 9.2 mg/L. It was also detected in 37% of the groundwater samples, although the maximum groundwater concentration is lower than the minimum recycled water concentration observed. However, because of this difference and because phosphate's transport characteristics are not well known, phosphate is ranked in category C) Inconclusive, and should be included for monitoring in the study.

Summary Data for Phosphate (mg/l), Category C

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0.45	9.205	7.943	14	18	100%
Groundwater	0	0	0.0395	0.21	19	37%

2.4.2. Nitrate and Nitrite

Nitrate is a common constituent in recycled water. Fertilizers and degradation of biomass also provide sources to surface and eventually groundwater. Nitrate is a concern for groundwater because parts of the Santa Clara Valley have groundwater concentrations above the USEPA MCL, which is 10 mg/L as N (44.3 mg/L as NO_3). The CA MCL for nitrate in drinking water is 45 mg/L as NO_3. Nitrate is known to cause short term health effects such as "blue baby syndrome" among infants (USEPA, 2007a).. Concentrations above the federal MCL have been observed in samples from groundwater wells within the Llagas Subbasin. The California DPH has set the draft maximum allowable nitrogen concentration for recycled water in groundwater recharge projects as 5 mg/L as N (22.1 mg/L as NO_3) (SCVWD, 2004).

Nitrate can leach through the soil into the groundwater over time, but there are several attenuation factors that reduce the potential impact, such as denitrification, crop uptake, and volatilization into nitrogen gas. Hence, the amount of nitrate that reaches groundwater is typically less than the amount applied (SCVWD, 2004). The effect of denitrification can vary from 0 to 90 percent of the total nitrogen concentration. Crop uptake can cause up to 50 percent attenuation. Due to these processes, the travel time for nitrate from the vadose zone to groundwater can be as much as 10 to 100 years (SCVWD, 2004).

In the environment, nitrate is converted into nitrite through microbial degradation. By a similar microbial process, nitrate can be produced from ammonia. Due to this generation mechanism, the ARWT Feasibility Project recommended the review of ammonia levels in recycled water sources. In a case study where groundwater was recharged to a basin through surface spreading using treated effluent, LACSD found that nitrate had increased with depth and ammonia decreased with depth. The case study also concluded that denitrification was not dominant at this site (SCVWD, 2004).

The ARWT Feasibility Project concluded that for agricultural purposes in the unconfined zone of the Santa Clara Subbasin, nitrate would not cause a significant impact to the groundwater because mass loading is expected to be low. For the Llagas Subbasin, the ARWT Feasibility Project determined that current groundwater concentrations of nitrate are higher than recycled water concentrations, and that recharging with recycled water may lead to improvement of the groundwater quality (SCVWD, 2004).

The data analysis shows that nitrate concentrations in recycled water frequently exceed the draft California DPH maximum allowable limit for the purpose of groundwater recharge (22.1 mg/L as NO_3). The median nitrate concentration in recycled water is 41 mg/L as NO_3. Nitrite concentrations in recycled water samples show a similar distribution and detection frequency to groundwater samples. Potential for nitrate in recycled water to affect nitrogen levels in groundwater exists. Nitrate and nitrite are ranked in category C) Inconclusive, because it is not clear how effective the attenuation factors will be in reducing these constituents. These parameters should be included for monitoring in the study.

Summary Data for Nitrate as NO_3 (mg/l), Category C

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	2.1	41.3	44.500	122	20	100%
Groundwater	0	20	23.5	429	14772	97.3%

Summary Data for Nitrite (As N) (µg/l), Category C

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	20.000	400	18	6%
Groundwater	0	0	124	48000	1571	6.2%

2.5. Anthropogenic Compounds

Anthropogenic compounds are man-made chemicals which are not naturally occurring. Several anthropogenic compounds are also endocrine disrupting compounds (EDCs), which are substances that mimic, block, stimulate, or inhibit natural hormones in the endocrine system (Metcalf and Eddy, 2007). EDCs can include steroid hormones as well as synthetic organic compounds, including certain plasticizers and surfactants. Additional research is needed in fate and transport data, standardized analytical methodology, removal kinetics, predictive models, synergistic effects, and determination of the toxicological relevance of EDCs.

2.5.1. Disinfection By-Products (DBPs)

Disinfection by-products (DBPs) are primarily dissolved organohalogens from oxidative breakdown of organic substances during treatment with a chemical disinfectant. DBPs include trihalomethanes, haloacetonitriles, haloketones, haloacetic acids, chlorophenols, aldehydes, trichloronitromethane, chloral hydrate, and cyanogen chloride. DBPs, formed by chlorination, depend on pH, temperature, reaction time, free and combined chlorine concentrations, ammonia concentration, DBP precursor concentration, and precursor type. DBPs are not expected to accumulate in the soil. Considering the transient time of water and degradation of DBPs in the vadose zone, most, but not all, DBPs are unlikely to cause a significant threat to groundwater (Metcalf and Eddy, 2007).

2.5.1.1. Trihalomethanes (THMs)

Trihalomethanes (THMs) are a group of chemicals that include chloroform, bromodichloromethane, dibromochloromethane, and bromoform. THMs are formed during chlorine disinfection. During chlorination, hypochlorous acid (i.e. the active disinfectant) reacts with natural organic matter (NOM) to form THMs. In the presence of bromide, hypochlorous acid can be converted to hypobromous acid, which also reacts with NOM to produce brominated THMs. THM concentrations generally increase when the chlorine dose, concentration of NOM, chlorine contact time, pH, temperature, and/or concentration of bromide ion increase (Sadiq and Rodriquez, 2004). US EPA's maximum contaminant level for total THMs is 80 μg/L (USEPA, 2003).

THMs volatilize quickly so their potential impact on groundwater through irrigation is low, particularly if there is a significant vadose zone thickness. However, there is little degradation of THMs once they have reached the saturated zone (AWWA, 2001). Pavelic et al. (2005) found that for an aquifer storage and recovery system, THMs had half lives ranging from < 1 to 65 days. The rate of removal for chloroform was the lowest and the rate of removal for bromoform was the highest.

In the recycled water samples included in the data analysis, THMs were detected in every sample analyzed at levels above the USEPA MCL for total THMs. Bromoform is the only compound that was not detected in 100 percent of the recycled water samples. Each of the THMs was also detected in groundwater samples, with frequencies ranging from 0.3% to 1.3%. The median and maximum concentrations were higher for each THM in recycled water samples. THMs are ranked in category C) Inconclusive, and should be included for monitoring in the study. Although it is clear there is reduction in THMs through the vadose zone, it is unclear if groundwater will be impacted.

Summary Data for Trihalomethanes, Total (µg/l), Category C

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	150	159.5	159.500	169	2	100%

Groundwater	0	0	0.0142	14.4	7068	0.6%

2.5.1.2. Haloacetic Acids (HAA5)

Haloacetic acids are common disinfection by-products formed through a reaction of natural organic matter in the wastewater with hypochlorous or hypobromous acid. HAA5 is a specific group of five haloacetic acids: monochloroacetic acid, dichloroacetic acid, trichloroacetic acid, monobromoacetic acid, and dibromoacetic acid. US EPA's maximum contaminant level for total HAA5 is 60 µg/L (USEPA, 2003). A sixth haloacetic acid, bromochloroacetic acid, is also frequently found in treated effluent, but is not included in the regulated HAA5 group. When bromochloroacetic acid is included with the other HAA5 compounds, they are referred to as the HAA6 group.

HAA5 compounds may degrade, but not completely, and the attenuation rates for HAA5 are low, especially in the saturated zone (SCVWD, 2004). Conversely, Pavelic et al. (2005) found that in an anoxic aquifer storage and recovery system, HAA5 were found to attenuate rapidly (half life < 1 day).

From the data analysis prepared for this study, all haloacetic acids appear in recycled water with greater frequency and higher concentrations than in groundwater. The median concentration for HAA5 in recycled water samples is slightly higher than the USEPA MCL (60 µg/L). Two haloacetic acids, dibromoacetic acid and bromochloroacetic acid, were detected in groundwater samples. Bromochloroacetic acid was detected in one third of the groundwater samples tested, although at much lower concentrations than those found in the recycled water samples. The maximum concentration of HAA5 observed in groundwater was 2.8 µg/L.

Because information on fate and transport of HAA5 is limited, HAA5 is ranked in category E) Insufficient Information, and should be included for monitoring in the study. Bromochloracetic acid should also be included in the analysis, since it has been observed in recycled water.

Summary Data for HAA5 (µg/l), Category E

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	1.7	62.45	83.361	232.3	18	100%

2.5.1.3. N-Nitrosodimethylamine (NDMA)

N-nitrosodimethylamine (NDMA) is a polar, uncharged organic compound, and is known to be a potent carcinogen. In response to the health concern of NDMA, The California Department of Public Health has set a drinking water notification level of 0.01 µg/L (CDPH, 2007). NDMA was formerly used in the production of liquid rocket fuel, antioxidants, and softeners for copolymers; but NDMA is currently used only for research purposes (USEPA, 2008). In addition, NDMA may form during water treatment using chlorination. Research suggests that NDMA can be formed by the reaction from (1) monochloramine, which is a common form of chlorine when ammonia-containing water is disinfected, and (2) simple amines like dimethylamine. As a result of industrial processes (e.g. printed circuit board manufacturing and waste treatment), NDMA is also present in wastewater effluent prior to disinfection (Sedlak et al., 2005). Precursors of NDMA mainly consist of complex organic compounds that contain nitrogen (Pehlivanoglu-Mantas et al., 2006). The precursors are found to be difficult to remove by conventional and advanced treatment processes. Ultraviolet (UV) radiation has been shown to be an effective method of removing NDMA, however the process is expensive (Metcalf and Eddy, 2007; Deeb et al., 2006).

A Southern California field study evaluated the leaching potential of NDMA in turfgrass soils irrigated with recycled water. The study attributed the lack of NDMA in leachate water to several potential mechanisms including degradation, plant uptake, gas phase diffusion in soil, and volatilization at the soil surface (Gan et al., 2006). The conditions in this field study were typical of irrigated turf grass. This study suggests that irrigation of landscapes with water containing NDMA will have minimal potential to cause groundwater contamination. Data suggests that NDMA does not sorb or biodegrade well once it is in the saturated zone. Where NDMA has been detected in groundwater, it has been found to be persistent. NDMA precursors are resistant to biotransformation, but can be partially removed in saturated soil columns (Gan et al., 2006; WateReuse Foundation, 2006). In a recycled water irrigation study performed in Hawaii, concentrations of NDMA were observed to decrease between the irrigated recycled water and the infiltrated water at a 5 foot depth (Brown and Caldwell, 2005). The study concluded that approximately 94 percent of the NDMA in applied recycled water was removed in the vadose zone, and that the soil in Central Oahu had sufficient rention time and soil carbon to remove complex organics such as NDMA from infiltrated water prior to reaching groundwater. In other studies, (Bradley et al., 2005; Kaplan and Kaplan, 1985), NDMA was found to biodegrade in laboratory settings in unsaturated and saturated soil samples under both aerobic and anaerobic conditions. More recently, field evidence of in situ NDMA biodegradation in the subsurface was supported in a separate study (Zhou et. al., 2009).

As an emerging contaminant, there are few groundwater samples analyzed for NDMA within the SCVWD database for the study area. In the database, NDMA was not detected in any of the groundwater samples. From April through June 2007 the Ground-Water Ambient Monitoring and Assessment (GAMA) program investigated groundwater quality in the San Francisco Bay region, and did not find any detections of NDMA in groundwater within the Santa Clara County (Ray et al, 2009). In the recycled water samples analyzed for NDMA, it was detected in all except one sample, with detections up to 0.49 µg/L. NDMA is ranked in category C) Inconclusive, and should be included for monitoring in the study. Under conditions where there is minimal potential for volatilization, NDMA has potential to affect the groundwater.

Summary Data for N-Nitroso dimethylamine (NDMA) (µg/l), Category C

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0.026	0.091	0.49	15	93%
Groundwater	0	0	0	0	17	0%

2.5.1.4. Bromate

Bromate (BrO_3^-) in recycled water forms from disinfection using ozonation. The precursors to bromate formation are bromide and ammonia ion. The World Health Organization has labeled bromate as a possible human carcinogen (Butler et al., 2005b). Recently, bromate contamination has been discovered in groundwater aquifers in Japan and the United Kingdom (Butler et al., 2005b, Mihoko et al 2006). Bromate has also been found exceeding protective standards in groundwater near an ore processing facility in the United States (USEPA, 2006a). Many countries have set a drinking water standard for bromate ranging from 10 to 25 µg/L. The maximum contaminant level (MCL) for bromate in the U.S. is 10 µg/L (USEPA, 2003). Bromate is highly soluble and stable in water. Conventional treatment has proven difficult in removing bromate (Butler et al., 2005a).

In the recycled water samples included in the data analysis for this study, bromate was detected in 11% of the samples at concentrations up to 3 µg/L. Bromate was not detected in any of the groundwater samples reviewed for this study. Because concentrations of bromate in recycled water are less than drinking water standards, it is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Bromate (µg/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.333	3	18	11%
Groundwater	0	0	0	0	19	0%

2.5.2. Pesticides and Associated Chemicals

Pesticides can enter groundwater from direct application to crops or from a wastewater stream that may contain traces of pesticides. Some pesticides can be difficult to remove completely in wastewater treatment, particularly since laboratory analytical methods for pesticides are very sensitive. Although there are many pesticides with the potential to impact groundwater quality, this section discusses four that have been detected in recycled water sources within the study area. A few additional pesticides, such as atrazine and glyphosate, were analyzed in recycled water samples, but were not detected. Other pesticides, such as the pyrethroids allethrin and bifenthrin, were not analyzed in recycled water samples for this data analysis.

2.5.2.1. Lindane (Gamma-BHC)

Lindane (Gamma-BHC) is applied as a pesticide for insects including wood-inhabiting beetles and lice on pets and livestock. It is also used on fruit and nut trees, vegetables, and timber. In the environment, lindane can be degraded by soil microbes. Lindane can also evaporate from the surface or can leach slowly into groundwater (USEPA, 2006b). A study of recycled water irrigation on golf courses in Florida found lindane and other pesticides at trace levels in the recycled water. Pesticides were detected in 52 percent of the shallow groundwater samples collected during that study. However, the golf courses also used pesticides to maintain turf. Hence, the contribution of pesticides from the recycled water cannot be determined (USGS, 1996). The federal and California MCL for lindane is 0.2 µg/L (USEPA, 2003, State of California, 2007). Lindane was detected in one of the recycled water samples included in the data analysis, with a concentration of 0.01 µg/L. Lindane was not detected in any groundwater samples. Because lindane was detected in only one sample, at a concentration below the MCL, it is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Lindane (Gamma-BHC) (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.001	0.01	16	6%
Groundwater	0	0	0	0	222	0.0%

2.5.2.2. Heptachlor Epoxide

Heptachlor epoxide is not manufactured directly, but is formed through the chemical and biological degradation of heptachlor in the environment. Heptachlor, once used as a non-agricultural insecticide, is currently only permitted to be used for fire ant control in buried electric power transformers and in underground cable boxes for televisions and telephones. In soil, heptachlor degrades readily to heptachlor epoxide, which can persist in upper soil layers for many years because it adsorbs strongly to soil and is resistant to biodegradation. Heptachlor epoxide can also be introduced into the food chain through plant uptake, and will bioaccumulate in animals. The current federal drinking water standard for heptachlor epoxide is 0.2 µg/L (USEPA, 2006b). The CA MCL for heptachlor epoxide is 0.01 µg/L. Heptachlor epoxide was detected in one of the recycled water samples analyzed, at a concentration of 0.01 µg/L.

Although the data analysis included over 1000 groundwater samples analyzed for this chemical, it was not detected in any samples. Because heptachlor epoxide is detected infrequently and adsorbs strongly to soil, it is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Summary Data for Heptachlor Epoxide (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.001	0.01	15	7%
Groundwater	0	0	0	0	1079	0.0%

2.5.2.3. *Aldicarb Sulfoxide*

Aldicarb sulfoxide is a microbial degradation product of aldicarb, a common pesticide used for aphids, mites, and some species of flies. The most common use of aldicarb is for cotton farming, although it is approved for use with other crops as well. Aldicarb sulfoxide is a potent neurotoxin at sufficient concentrations. The transformation of aldicarb to aldicarb sulfoxide occurs relatively quickly in the environment. The degradation of aldicarb sulfoxide occurs more slowly, by nonbiological processes (USGS, 1995). Aldicarb sulfoxide was detected in four of the 18 recycled water samples analyzed. It was also detected in some groundwater samples, but at a much lower frequency (0.4%). Because of the limited information of fate and transport of aldicarb sulfoxide, it is ranked in category E) Insufficient Information, and should be included for monitoring in the study.

Summary Data for Aldicarb Sulfoxide (µg/l), Category E						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.2778	1.5	18	22%
Groundwater	0	0	0.0122	3	738	0.4%

2.5.2.4. *Terbuthylazine*

Terbuthylazine is an herbicide that inhibits photosynthesis in plants. It is used to control algae, fungi, and bacteria in commercial and industrial water cooling systems. Discharge of water containing terbuthylazine to sewage systems is prohibited without first notifying the treatment plant authority. Terbuthylazine has been shown to degrade in soil, at varying rates depending on the temperature, moisture level, microbial activity, pH, and aeration state. Adsorption of terbuthylazine onto soil is dependent on the organic material content. Terbuthylazine is also degraded through exposure to sunlight, with a half-life of approximately three months (World Health Organization, 1998). Terbuthylazine was detected in two of the four recycled water samples analyzed, as shown in Appendix I-C. Data for terbuthylazine in groundwater were not available for the data analysis. For this reason, terbuthylazine is ranked in category C) Inconclusive, and should be included for monitoring in the study.

Summary Data for Terbuthylazine (µg/l), Category C						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0.05	0.050	0.1	4	50%
Groundwater	NA	NA	NA	NA	NA	NA

2.5.3. Hormones and Pharmaceutically Active Compounds (PhACs)

Hormones are EDCs, and can either be natural or synthetic. Concentrations of natural and synthetic hormones are generally low in recycled water. It is suspected that most of these hormone compounds absorb to soil and biodegrade quickly. One study found that estrone, an estrogenic hormone, degrades rapidly in aerobic soils. Anaerobic conditions resulted in little or no degradation of estrone (Ying, 2006). In a soil column study using three feet (one meter) soil columns operated under different conditions, gemfibrozil, ibuprofen, and noaproxen were believed to biotransform after 6 days of travel time as indicated by the lack of detection below the quantification limit under anoxic and oxic conditions. Biotransformation was identified as the main attenuation mechanism for these constituents under biotic conditions (Hoppe-Jones, et al, date unspecified). In the data analysis, estrone was detected in one groundwater sample and one recycled water sample, at concentrations of 0.0016 and 0.011 µg/L, respectively. Since it is detected infrequently, and has fate and transport characteristics that would limit the transport to groundwater, estrone can be classified in category D) Minimal Potential for Impact.

Pharmaceutically active compounds (PhACs) include antibiotics, anti-inflamatories, x-ray contrast media, and antidepressants. Some PhACs, like contraceptives and steroids, are also EDCs. The majority of PhACs are more hydrophilic than other anthropogenic compounds, which makes them less subject to adsorption, but possibly more biodegradable (Metcalf and Eddy, 2007). However, most steroids have a higher octanol-water partition coefficient and will sorb readily. In one study with steroidal hormones (17 beta-estradiol, estriol, and testosterone), adsorption to the porous media was the dominant removal mechanism. Further attenuation occurred in the presence of bioactivity regardless of the redox conditions whether the soil was aerobic or anoxic. Attenuation with bioactivity was not dependent on the type of organic carbon matrix (hydrophobic acids, hydrophilic carbon, or colloidal carbon) (Mansell et al., 2004).

Six compounds that can be classified as PhACs were detected in the recycled water samples included in the data analysis: caffeine, carbamazepine, carisoprodol, gemfibrozil, ibuprofen, and naproxen. Of these compounds, ibuprofen was detected most frequently, in 27% of recycled water samples analyzed. Caffeine, carisoprodol, and naproxen were each detected in only one sample. None of these compounds were detected in the groundwater samples. Due to the limited information on fate and transport characteristics, PhACs are ranked in category E) Insufficient Information, and should be included for monitoring in the study.

2.5.4. Industrial Chemicals

Removal of industrial chemicals (detergent compounds, their metabolites, and halogenated compounds) usually relies on photodegradation, affinity toward absorption to soil material, and biodegradability. Some of these chemicals degrade quickly while others may persist longer. Current research suggests that the soil environment can reduce most industrial chemicals to low levels. The ARWT Feasibility Project reported concentrations of detergent metabolites to decrease significantly as they migrate through the vadose zone, but reduction was not complete (SCVWD, 2004). Some industrial chemicals are also endocrine disruptors (Metcalf and Eddy, 2007).

2.5.4.1. Volatile Organic Compounds (VOCs)

Volatile organic compounds (VOCs) include a list of dozens of chemicals, which are frequently groundwater contaminants at industrial sites. Although recycled water samples have been analyzed for a comprehensive list of VOCs, only two of these chemicals were detected in the recycled water sources: carbon tetrachloride and xylenes.

Carbon tetrachloride is a clear heavy organic liquid used in fire extinguishers, nylon manufacturing, rubber cement, insecticides, and cleaning agents. Carbon tetrachloride evaporates quickly from surface water and soil. It does not adsorb well to soil, and hence may leach into groundwater. Carbon tetrachloride does not tend to accumulate in aquatic organisms (USEPA, 2006b). The federal MCL drinking water standard for carbon tetrachloride is 5 µg/L (USEPA, 2003). The CA MCL for carbon tetrachloride is 0.5 µg/L (State of California, 2007). In the data analysis for this study, carbon tetrachloride was detected in one of the nineteen recycled water samples tested, at a concentration of 0.69 µg/L, which is above the CA MCL. Carbon tetrachloride is detected infrequently in both recycled water and groundwater with 0.7% detection in groundwater and 6% in recycled water. The mean concentration of carbon tetrachloride in groundwater is 0.04 µg/L compared to 0.041 µg/L in recycled water. Because carbon tetrachloride was found in recycled water at similar concentrations to those of groundwater, carbon tetrachloride is ranked in category D) Minimal Potential for Impact, and is not recommended for monitoring in the study.

Xylenes are a group of similar compounds, used predominantly as a solvent. There are three isomers (meta-xylene, para-xylene, and ortho-xylene), which can be quantified individually but are more frequently reported cumulatively as total xylenes. In the environment, xylenes will evaporate when released into the soil or water. However, they can leach into the groundwater and persist there for several years. Xylenes tend not to accumulate in aquatic organisms (USEPA, 2006b). The federal and CA MCL drinking water standard for xylenes is 10,000 µg/L and 1,750 µg/L respectively (USEPA, 2003; State of California, 2007). Xylenes were detected in one of the recycled water samples included in the data analysis, at a concentration of 3.8 µg/L. Concentrations of xylenes have also been detected in groundwater, but those concentrations are most likely due to localized impacts with high concentrations. Xylenes were detected in only 1.1% of groundwater samples. Because xylenes were found in recycled water in low amounts and low frequency, xylenes are ranked in category D) Minimal Potential for Impact, and are not recommended for monitoring in the study.

Summary Data for Carbon Tetrachloride (µg/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency

2.5.4.2. 1,4-Dioxane

1,4-Dioxane is a solvent stabilizer compound commonly associated with VOCs, particularly 1,1,1-trichloroethane, and is a probable human carcinogen. It is a water contaminant that is used in a variety of industrial and commercial products. 1,4-Dioxane is highly soluble and resistant to biodegradation. 1,4 Dioxane can be successfully removed by advanced oxidation processes (Metcalf and Eddy, 2007). Although several samples of recycled water from the study area have been analyzed for 1,4-dioxane, it has not been detected in any samples. Hence, it is included in category D) Minimal Potential for Impact.

2.5.4.3. Plasticizers

Plasticizers are chemicals used to increase the plasticity of certain materials such as plastics and cement. Common plasticizers include di(2-ethylhexyl)phthalate (DEHP), N-butyl benzenesulfonamide (NBBS) and bisphenol-A (BPA). DEHP is widely used in the manufacture of polyvinyl chloride plastics. In the environment, DEHP does not evaporate, but it strongly adsorbs to soil, and has very low solubility in water. For these reasons, there is minimal potential for DEHP to leach into groundwater. In the presence of water, DEHPs can be biodegraded within weeks. However, in the food chain it can accumulate to elevated concentrations in aquatic organisms (USEPA, 2006b). DEHP was detected in two of the recycled water samples used for the data analysis. Concentrations have been observed in groundwater at much higher concentrations, although with much lower frequency. DEHP is ranked in category D) Minimal Potential for Impact. Monitoring for this constituent is not needed.

NBBS is a water-soluble compound used in nylon production. It enters the environment when water comes into contact with NBBS-containing plastics, such as leaching of landfills where NBBS-containing plastics have been disposed. In a previous SCVWD study, NBBS was detected in surface water, recycled water and groundwater. The study found levels of NBBS in samples of recycled water that are generally similar to those in surface water (SCVWD, 2006). Little information is available regarding the transport of NBBS through soil, although given its solubility and common presence in surface water and groundwater, it appears to have minimal, if any, attenuation through the vadose zone. NBBS was detected in two thirds of the samples included in the data analysis, and in one of the ten groundwater samples. Although detections were more frequent in recycled water samples, the highest observed concentration of NBBS was in the groundwater sample, at 0.5 μg/L. Because of the limited information in fate and transport, NBBS is ranked in category E) Insufficient Information, and should be included for monitoring in the study provided a laboratory capable of testing this constituent is identified.

BPA is used in polycarbonate plastic and epoxy resins. BPA is also classified as an estrogen-like EDC. In a laboratory batch equilibrium study of sorption on soils, BPA showed weak sorption characteristics, but showed rapid degradation in soils under aerobic conditions. Under anaerobic conditions, BPA showed very little degradation (Kookana and Ying, 2005). The 2006 SCVWD study detected BPA in one groundwater sample (SCVWD, 2006). In the data analysis conducted for this project, BPA was not observed in any recycled water sources. Hence, BPA is ranked in category D) Minimal Potential for Impact, and monitoring is not needed.

Summary Data for Di(2-Ethylhexyl)Phthalate (μg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.093	0.7	15	13%
Groundwater	0	0	0.147	27.1	1552	2.1%

Summary Data for NBBS (μg/l), Category E						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0.0075	0.032	0.27	12	67%
Groundwater	0	0	0.05	0.5	10	10%

2.5.4.4. Perfluorochemicals (PFCs)

Perfluorochemicals are a group of organic compounds that have hydrogen-based structures and are partially or fully fluorinated. PFCs are hydrophobic and oleophobic, which makes them useful in products such as non-stick surfaces and stain-resistant carpeting. PFCs include perfluorooctanesulfonate, perfluorooctanoate, perfluorononanoate, perfluorohexane sulfonate, and perfluorooctane sulfonamide (Nakata et al., 2006).

PFCs have a chemical structure that makes them very resistant to breakdown in the environment. PFCs are suspected to bioaccumulate, and they have been detected in fish, birds, marine mammals and humans (Luthy, 2007). Because PFCs are an emerging set of contaminants, information on fate and transport characteristics is limited. In a previous study conducted by SCVWD, PFCs were found in recycled water, surface water, and groundwater. However, the highest concentrations of PFCs were found in recycled water sources, particularly perfluorooctanesulfonate (PFOS) and perfluorooctanoate (PFOA), at concentrations of 340 and 110 ng/L, respectively. PFOS was also detected in groundwater at a concentration of 26 ng/L (SCVWD, 2006). In surface water, PFCs have been detected as high as 129 ng/L in Upper Silver Creek (SCVWD, 2006). Since only a few recycled water samples and one groundwater sample have been analyzed for PFCs, a full data analysis could not be performed. Because there is limited information on fate and transport of PFCs, they are ranked in category E) Insufficient Information and should be included for monitoring in the study.

2.5.4.5. Nitrilotriacetic acid (NTA) and Ethylenediaminetetraacetic Acid (EDTA)

Ethylenediaminetetraacetic acid (EDTA) and nitrilotriacetic acid (NTA) belong to aminopolycarboxylic acids which are multidentate synthetic organics (National Center for Sustainable Water Supply [NCSWS], 2001). Both EDTA and NTA are commonly present in domestic and industrial cleaning agents. They are found in laundry detergents, agricultural fertilizer, and pulp and paper production. Previous studies have shown that EDTA is relatively persistent in the subsurface, but has been shown to rapidly photodegrade when present in a complex with ferric iron. NTA has a relatively high susceptibility to biodegradation in soil and surface water (AWWA, 2001). A study of a recharge program at the Sweetwater Recharge Facility in Tucson, Arizona, showed EDTA removal of 0 and 80 percent at 3 meters and 38 meters below ground surface, respectively (Hyung, 2003). The same study showed NTA removals of 75% and 98% at the same respective depths. Similarly, another study found significant attenuation of NTA during river water infiltration and groundwater transport (Ding, 1999).

EDTA was detected in all recycled water samples, and over half of the groundwater samples. In general, EDTA concentrations in recycled water were much higher than groundwater concentrations. NTA results were not available for the data analysis. Both NTA and EDTA are ranked in category C) Inconclusive, and should be included for monitoring in the study.

Summary Data for EDTA (µg/l), Category C						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	6	19.5	105.383	305	6	100%
Groundwater	0	5	4.736	13	11	55%

2.5.4.6. Naphthalenedicarboxylic Acids (NDCs)

Naphthalenedicarboxylic acids (NDCs) are industrial chemicals that are suspected to be an oxidative transformation product of polycyclic aromatic hydrocarbons (PAHs), a constituent of petroleum products. Previous studies have detected NDCs in recycled water sources. Limited information is available on the environmental fate of NDCs. A laboratory study found that some NDCs can be slowly degraded biologically, but the results showed poor reproducibility. A field-scale study of recycled water application in Tucson, Arizona showed that a large percentage of NDCs were removed within the first 10 feet of the subsurface, but below that, the degradation was significantly slower (AWWA, 2001). A laboratory study of microbial degradation has been performed on one form of NDC, which identified two strains of bacteria that may degrade NDCs, although slowly and inefficiently. The microbial study results also showed poor reproducibility (Lefèvre et al., 1999). Other than these studies, very little information is available regarding the fate of NDCs in the environment. Analytical results for NDCs were not available for the data analysis. NDCs are ranked in category E) Insufficient Information, and should be included for monitoring in the study provided a laboratory capable of testing for this constituent is identified.

2.5.4.7. Perchlorate

Perchlorate (ClO_4^-) is a highly oxidized chlorine oxyanion used as an oxidizer in solid propellants for rockets, missiles, explosives, and pyrotechnics. Perchlorate can also be distributed through the use of certain fertilizers which are derived from evaporite deposits. Once in the environment, perchlorate is highly soluble and adsorbs poorly to soil. For these reasons, when perchlorate reaches groundwater, it can spread over large distances. Anaerobic biological reactors and ion exchange are effective measures in removing perchlorate. There is also concern for perchlorate accumulation in food plants because it is a human exposure route (Metcalf and Eddy, 2007).

Groundwater in portions of the Llagas Subbasin has been impacted with perchlorate, with several drinking water source wells being shut down due to concentrations of perchlorate. The State of California has issued an MCL for perchlorate at 6 µg/L. Perchlorate has been detected in two recycled water sources included in this study: PARWQCP and SWPCP. The detection frequency for groundwater is higher than for recycled water, but that is likely due to the perchlorate impact on the Llagas Subbasin. Due to its transport characteristics and presence in recycled water, perchlorate is ranked in category A) Significant Potential for Impact, and should be included for monitoring in the study.

Summary Data for Perchlorate (µg/l), Category A						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.922	12.3	18	11%
Groundwater	0	0	0.707	13	2223	13.0%

2.5.4.8. *Hexachlorocyclopentadiene*

Hexachlorocyclopentadiene is a semi-volatile compound used in multiple industrial processes, including manufacture of insecticides and flame retardants. In the environment, hexachlorocyclopentadiene sorbs strongly to soils, and once there, degrades quickly by either chemical hydrolysis or biodegradation. This chemical degrades even more quickly when exposed to sunlight, with a half-life in the range of a few minutes. In surface water, hexachlorocyclopentadiene is attenuated either through volatilization or photolysis (USEPA, 2006b). In the data analyzed for this study, hexachlorocyclopentadiene was detected in one of the 14 recycled water samples, with a concentration of 0.1 µg/L. The chemical was not detected in any groundwater samples. Due to strong attenuation of hexachlorocyclopentadiene, this constituent is ranked in category D) Minimal Potential for Impact. Monitoring for this constituent is not needed.

Summary Data for Hexachlorocyclopentadiene (µg/l), Category D						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.007	0.1	14	7%
Groundwater	0	0	0	0	1127	0.0%

2.5.4.9. Methyl Tertiary-Butyl Ether (MTBE) and Other Oxygenates

Oxygenates like methyl tertiary-butyl ether (MTBE) are added to gasoline to achieve more complete combustion and to improve air quality. Widespread use of oxygenates has lead to contamination in the environment, and consequently, some drinking water sources. Oxygenates are polar compounds, hence they adsorb poorly to soils and can migrate through aquifers easily (Metcalf and Eddy, 2007). However, most oxygenates volatilize readily, and they have been shown to degrade biologically, although not under natural conditions (USEPA, 2004).

The oxygenates included in the data analysis are MTBE, tertiary amyl methyl ether, ethyl tertiary butyl ether, and diisopropyl ether. None of these oxygenates were detected in recycled water samples. Hence, there is limited potential to impact groundwater.

2.5.4.10. Organophosphates

Tris(3-chloropropyl)phosphate and tris(2,3-dichloropropyl)phosphate are organophosphates that are suspected to be carcinogenic. Trisphosphates are used primarily in flame retardants but can also be found in specialized rubber products, elastomers, fiberglass resins, industrial paints, surface coatings and sealants (National Industrial Chemicals Notification and Assessment Scheme [NICNAS], 2001). These chemicals have been detected in surface water, groundwater, and recycled water, with the highest concentrations in recycled water (SCVWD, 2006). The ARWT Feasibility Project found that the concentrations of these chemicals in recycled water pose no health risk (SCVWD, 2004).

A Stanford University study of effluent discharge to the Santa Ana River found that trisphosphates were detected regularly in recycled water. The study also found that under wetland treatment, trisphosphates were partially removed (Gross et al, 2004). Other than this study, little information is available regarding the fate and transport of trisphosphates in the environment.

In the data analysis prepared for this study, trisphosphates were detected in all recycled water samples except one, with maximum concentrations of 0.46 µg/L of tris(2,3-dichloropropyl)phosphate and 0.42 µg/L of tris(3-chloropropyl)phosphate. Trisphosphates were not detected in any groundwater samples.

Because of the limited information in fate and transport, trisphosphates are ranked in category E) Insufficient Information, and should be included for monitoring in the study provided a laboratory capable of testing this constituent is identified.

Summary Data for Tris(2,3-dichloropropyl)phosphate (µg/l), Category E						
	Minimum	Median	Mean	Maximum	Count	Detect Frequency

Groundwater	0	0	0	0	10	0%

2.5.4.11. Surfactants

Surfactants are a common component of most detergents. In the environment, surfactants can form a surface film, which reduces oxygen transfer. They can also alter the hydraulic properties of soils. Surfactants are often monitored collectively as methylene blue active substances (MBAS). MBAS are a group of chemicals that react with methylene blue under specific testing conditions. A study in Florida found low concentrations of MBAS in recycled water. Although MBAS were also found at low concentrations in groundwater, the study concluded they were not attributable to recycled water use, but rather runoff from residential areas or nearby streets (USGS, 1996).

Alkylphenol ethoxylates (APEOs) are a specific type of nonionic surfactants used in domestic and industrial products. APEOs and some of their metabolites are suspected to be EDCs. During wastewater treatment and in the environment, APEOs degrade into alkylphenol ethoxycarboxylates (APECs), carboxyalkylphenol ethoxycarboxylates (CAPECs), alkylphenols (nonylphenol (NP) and octylphenol (OP)), alkylphenol mono-ethoxylate (AP1EO), alkylphenol di-ethoxylate (AP2EO), and alkylphenol tri-ethoxylate (AP3EO) (Ying et al., 2002). The biotransformation of APEOs to APECs occurs under aerobic conditions during wastewater treatment, and has also been shown to occur in the environment under wetland treatment (Gross et al, 2004). Halogenated APECs and halogenated APEOs, which have both been found in recycled water samples, are chlorinated or brominated forms of APECs and APEOs created during wastewater disinfection.

The physiochemical properties of APEOs, particularly the high octanol-water coefficients (K_{ow}), suggest that APEOs can partition effectively into the soil. Previous studies have shown concentrations of APEOs in treated wastewater effluents ranging from <0.1 to 369 µg/L, and in sediments from <0.1 to 13,700 µg/kg (Ying et al., 2002).

Compared to APEOs, the degradation products have higher toxicity and are more persistent than the parent compounds. The degradation products also sorb more readily to soils and sediments (Thiele et al., 1997). In one study of soil aquifer treatment in Arizona, APEOs were removed in both anoxic and oxic conditions. Generally, the length of ethoxycarboxylate chain has been found to decrease with depth as water percolates through the vadose zone. At depths greater than 3 meters only the alkylphenoxy acetic acids (AP1ECs), carboxyalkylphenoxy acetic acids (CAP1ECs), and alkylphenols (APs) remained. Under aerobic conditions, NP and OP were found to decrease by 80 percent within a three meter depth. Under anoxic conditions, APs were found to increase by 38 percent at 3 meters below ground surface, and APEC and CAPEC were found to decrease by more than 95 percent at the same depth. For treatment of APEOs in groundwater recharge applications, alternating flooding and drying cycles for recharge appears to enhance APEO removal (Montgomery-Brown et al., 2003).

At the Las Positas Golf Course in Livermore, CA, which was irrigated with recycled water from the Livermore Water Reclamation Plant, concentrations of NP, AP1EC, and AP2EC were observed to reduce substantially from the recycled water to the groundwater (Hudson et al, 2005; LLNL, 2006). The attenuation of APEO metabolites was attributed to sorption. In addition, estrogenic bioassay tests showed reduction in estrogenic response from the recycled water to the groundwater.

In Gilroy, where the South County Regional Wastewater Authority (SCRWA) provides water recycling for irrigation, five groundwater wells from a farm location, and three groundwater wells from Christmas Hill Park were monitored for trace organic compounds (LLNL, 2006). The groundwater at these locations occurs at depths of less than 20 feet below ground surface. NP, NP1EC, and NP2EC were detected in the shallow groundwater. Detections of low level NP may have been sampling artifacts.

A study of a recharge program at the Sweetwater Recharge Facility in Tucson, Arizona, showed APEC removals of 30% and 93% at 3 and 38 meters below ground surface, respectively (Hyung, 2003). Similarly, a different study found significant attenuation of APECs during river water infiltration and groundwater transport (Ding et al., 1999). A previous SCVWD study detected APEOs and their degradation products consistently in recycled water sources, but did not detect these compounds in the surface or groundwater (SCVWD, 2006).

Concentrations of total surfactants were detected in every recycled water sample included in the data analysis, with concentrations ranging from 94 to 357 µg/L. Individual surfactants were also occasionally detected in the groundwater samples, but with lower concentrations and lower frequency. However, the reporting limit for the total surfactants analysis is much higher than the reporting limits for individual surfactants.

In addition to the general analysis for surfactants, some samples were analyzed for specific APEOs and their metabolites. AP1EO, AP2EO, and AP3EO were each detected in 10% to 13% of the recycled water samples, and AP1EO was detected in one groundwater sample. Overall, APEOs were detected in 20% of recycled water samples. APECs were detected more frequently, in 64% of the recycled water samples, and in 40% of groundwater samples. Specific APECs, identified by their mass-charge ratio, were also analyzed, and detection frequencies ranged from 40% to 50% in recycled water samples. Halogenated AP/APEOs were detected in 17% of the recycled water samples and halogenated APECs were detected in 92%. The halogenated AP/APEOs and APECs were not detected in any groundwater samples. Concentrations of NP and OP were detected more frequently in groundwater samples than recycled water samples, with two thirds of the groundwater samples showing some detection. Because surfactants and their degradation products have significantly varying fate and transport characteristics, APEOs, APECs, NP, and OP are ranked in category C) Inconclusive, and should be included for monitoring in the study using MBAS to measure surfactants.

2.6. Pathogens

Microbiological contaminants, including bacteria and viruses, are occasionally present in recycled water sources. Some microbial species, such as *Clostridium perfringens*, have resistance to chlorine disinfection and are more frequently found in recycled water sources. These contaminants have also impacted groundwater at some locations where recycled water is used for groundwater recharge.

2.6.1. Bacteria and Parasites

In the laboratory, bacteria can be monitored using several techniques. Heterotrophic plate count is one of the simplest and most frequently used methods. The heterotrophic plate count is a measurement of the total number of bacteria present in a water sample. It is usually reported in colony-forming units per milliliter (CFU/mL). In the data analysis for this study, recycled water sources showed much higher maximum heterotrophic plate count than groundwater samples. However, the median values for recycled water and groundwater were similar.

Three coliform counts are frequently used to monitor bacteria presence: total coliforms, fecal coliforms, and *E. Coli* coliforms. Total coliforms include a large group of bacterial species. Fecal coliforms is a measurement that isolates a specific subgroup of coliforms originating in feces. *E. Coli* is a specific species that can be isolated and measured. In the data analysis for this study, total coliforms were detected in a third of recycled water samples, and in one groundwater sample. Fecal coliforms and *E. Coli* coliforms were below detection in all except one of the recycled water samples. Legionella, another bacterium known to cause lung and gastrointestinal infections, was detected in one of the samples from SWPCP, but no other recycled water or groundwater samples.

Using high-volume sampling techniques with low detection limits, a study of several water reclamation plants in the Los Angeles area found that total coliforms were detected regularly, although the concentrations were always below the California Title 22 limits for reuse. This study also found evidence of microbial impact in groundwater in the area where recycled water was being used for recharge. A similar study in Arizona found a direct correlation between bacterial indicators in groundwater and distance from the recharge point of recycled water. However, the coliform concentrations in the groundwater at both sites were below the detection limits for routine monitoring. The concentrations could only be quantified using high-volume sampling techniques (AWWA, 2001).

In addition to the coliform counts for bacteria, there are two protozoan parasites that have been monitored in recycled water sources: cryptosporidium and giardia. Both of these are genera of pathogens that cause intestinal disease. In water, these protozoa are often found in a spore-like phase as cysts (giardia) or oocysts (cryptosporidium). Giardia cysts and cryptosporidium oocysts can survive some wastewater disinfection processes like chlorination. In the recycled water samples examined for the data analysis, giardia and cryptosporidium were both detected at low concentrations. Giardia was detected more frequently, in 27% of the samples. Neither of these pathogens were detected in groundwater. There is not enough information concerning the fate and transport of bacteria and parasites to evaluate the impacts to groundwater. Hence, bacteria and parasites are ranked as category E) Insufficient Information, and should be included for monitoring in the study.

Summary Data for Giardia (cyst/L), Category E

	Minimum	Median	Mean	Maximum	Count	Detect Frequency

2.6.2. Viruses

Bacteria and parasites can be inactivated through death or dilution relatively quickly in the environment. However, the survival of viruses poses a concern (Metcalf and Eddy, 2007). There is less information available for the fate and transport of viruses than for bacteria. Although virus testing was a part of both the Los Angeles and Arizona studies discussed above, neither study found significant evidence of virus impacts caused by recycled water application. In other laboratory experiments, some viruses have been found to adsorb readily to soil particles, while others transport more quickly.

A field-scale experiment on virus transport in the environment was performed in Los Angeles County in 1997 (AWWA, 2001). The experiment included spiking recycled water with a concentrated stock solution of bacteriophage (a virus that targets bacteria) as well as a bromide tracer, and applying it within a large recharge facility. The bacteriophage used in this experiment was a surrogate for human viruses commonly found in recycled water. Groundwater concentrations at the site were monitored at depths of five and ten feet over a period of two days. Concentrations of the virus were detected within 4 hours at 5 feet below ground surface, and in 6 hours at 10 feet below ground surface. The maximum virus concentration observed in both wells was approximately two orders of magnitude less than the concentration discharged at the surface. Since the bromide concentrations did not change significantly over the 10-foot interval, it was determined that the reduction in concentrations was not caused by dilution, but the virus was attenuated by removal and/or inactivation. Below 10 feet, the virus was also detected, but not at quantitative levels (AWWA, 2001).

The data analysis for this study included results for total culturable virus assay. The results were below detection for all recycled water samples, but a value of 0.11 most-probable-number per 100 liters was found in one groundwater sample. Since viruses were not detected in any recycled water samples, viruses are ranked in category D) Minimal Potential for Impact, and do not need to be monitored.

2.7. Radioactives

Alpha emitters are radionuclides that give off alpha particles. An alpha particle is similar to a helium nucleus with two protons and two neutrons. Alpha emitters, which can be natural or anthropogenic, include americium-241, plutonium-236, uranium-238, thorium-232, radium-226, radon-222, and polonium-210. Alpha emitters are used in industry as static eliminators, in smoke detectors, and in cancer treatment (USEPA, 2007b).

Alpha particles do not travel far in the environment; their energy is quickly lost in the air, within a few centimeters. Once an alpha particle has lost its energy, it becomes helium. Generally, external exposure of alpha particles is less of a concern than internal exposure because they lack the energy to penetrate the outer layer of human skin. However, inhalation, ingestion, or absorption into blood stream can increase the risk of cancer. In particular, inhalation of alpha emitter has been known to cause lung cancer (USEPA, 2007b).

Beta emitters are radionuclides which give off beta particles. Beta particles are smaller than alpha particles, having 1/2000 of a proton’s mass. Beta emitters, which can be natural or anthropogenic, include tritium, cobalt-60, strontium-90, carbon-14, technetium-99, iodine-129, iodine-131, cesium-137, and phosphorus-32. Beta emitters are used in medical diagnosis, imaging and treatment (USEPA, 2007b). Beta particles may travel several feet before they hit solid material. Beta radiation can have acute and chronic health effects. Direct exposure to beta particles is considered hazardous; strong sources of beta particles can redden or burn skin. Inhalation and ingestion are of greater concern because they damage living tissue (USEPA, 2007b).

In a previous SCVWD study, levels of gross alpha and beta emitters in surface water, groundwater, and recycled water were found below drinking water regulations or threshold values as determined by the laboratory (SCVWD, 2004). The USEPA and CA MCL for gross alpha particle activity are 15 picoCuries per liter. The MCL for beta particles is specified in millirems per year of exposure, but as a general guideline, gross beta emissions less than 50 picoCuries per liter are considered safe for drinking water (USEPA, 2003). Both alpha and beta radiation were found at higher levels in recycled water samples than in groundwater samples in the data analysis. However, the maximum detected values for both measurements were below the respective MCLs.

Radium-228, a beta-particle-emitting radioactive metal, was detected in one of the recycled water samples at 1.1 picoCuries per liter, but since only four samples were analyzed for radium-228, there is insufficient data to fully characterize it. A specific MCL has not been established for radium-228, but the MCL for combined radium-226 and radium-228 is 5 picoCuries per liter. Since radium-226 was not detected in any recycled water samples, all recycled water samples were below the MCL for radium-226 and radium-228. Because the radioactive concentrations in recycled water are less than drinking water standards, they are ranked as category D) Minimal Potential for Impact, and are not recommended for monitoring in the study.

Summary Data for Radium 228 (pci/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	0	0.275	1.1	4	25%
Groundwater	0	0	0.0920	5.67	687	9.8%

Summary Data for Alpha, Gross (pci/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	0	3.2	2.59	6.7	17	65%
Groundwater	0	0.72	1.49	470	3965	70%

Summary Data for Beta, Gross (pci/l), Category D

	Minimum	Median	Mean	Maximum	Count	Detect Frequency
Recycled Water	5.2	11	11.83	19	17	100%
Groundwater	0	1.105	2.09	34	562	64%

2.8. Conclusions

The constituents of most concern that need to be monitored are those which are likely to affect groundwater, category A) Significant Potential for Impact. Constituents that belong to category A) are those that are likely to negatively impact groundwater resources based on the available information on the fate and transport pathways and the data analysis. Those that fall in this category include ions (e.g. magnesium, calcium, sodium, sulfate, chloride), DOC, TOC, TDS, and perchlorate. Magnesium, calcium, and sodium are especially of concern as they may potentially affect soil permeability.

In addition to constituents in category A), constituents that fall in categories C) Inconclusive and E) Insufficient Information should also be monitored. Constituents that belong to either of these categories have a potential to negatively impact groundwater. However, there are too many unknowns with these constituents to determine with confidence whether or not there will be negative impacts. Constituents in category C) include boron, surfactants (represented by MBAS), THMs, terbuthylazine, cyanide, phosphate, nitrate, nitrite, EDTA, NTA, and NDMA. Constituents in category E) include aldicarb sulfoxide, HAA5, bromochloroacetic acid, PHaCs, NDCs, bacteria and parasites, NBBS, PFCs, and trisphosphates. More studies are needed of the constituents in category E) to properly evaluate their effects on groundwater.

Category D) are constituents that are not expected to impact groundwater resources either because 1) constituent concentrations in recycled water are less than or similar to those in groundwater or drinking water standards or 2) fate and transport mechanisms suggest that constituents will be attenuated before reaching groundwater. Constituents in these categories include bromate, radioactives, hardness, TSS, silica, metals (aluminum, cadmium, copper, iron, lead, manganese, nickel, zinc), fluoride, lindane, heptachlor epoxide, 1,4-dioxane, DEHP, BPA, hexachlorocyclopentadiene, VOCs (xylenes and carbon tetrachloride), oxygenates (MTBE, tertiary amyl methyl ether, ethyl tertiary butyl ether, diisopropyl ether), turbidity, viruses, and estrone.

Category B) includes alkalinity, DO, ORP and pH. These constituents are important to monitor as they provide insight to how other constituents in recycled water will behave through soil.

3. SOIL AQUIFER PLUGGING

In addition to the potential effects recycled water use can have on groundwater, some characteristics of recycled water have been shown to cause reductions in hydraulic conductivity in surface soils. Over time, this effect may actually cause a change in the quantity of water that percolates from the surface and recharges groundwater. Aquifer soil plugging can originate from three mechanisms: chemical plugging due to clay expansion/dispersion and/or mineral precipitation, physical plugging due to particulate matter, and biological plugging due to bacterial growth (SCVWD, 2004).

3.1. Clay Expansion / Dispersion

The potential for clay expansion and dispersion caused by contact with recycled water has been investigated extensively in a previous study conducted on behalf of SCVWD (Geologica, 2003). In soils with expansive clays, hydraulic conductivity can be reduced as a result of cation exchange resulting in swelling from increased interparticle spaces between clay layers, effects of dispersion, or destruction of structural aggregates.

Hydraulic conductivity changes are caused by changes in the size of the intra-particle spacing, which separates clay layers or inter-particle spaces. When this space expands, the pore sizes are reduced, which reduces the hydraulic conductivity. Clay surfaces are negatively charged, and cations such as sodium, magnesium, and calcium are attracted to this space. When sodium is adsorbed to the inter-particle surfaces, replacing calcium and magnesium ions, the spacing expands and the clay swells. Hence, recycled water with high sodium concentrations (or high TDS levels) and a high sodium adsorption ratio (SAR) can reduce hydraulic conductivity. SAR describes the concentration of sodium relative to calcium and magnesium. Table I-2-3 of this report includes calculated SAR values prepared using the analyses for the recycled water samples included in the data analysis. Expansion is also dependent on the exchangeable sodium percentage which characterizes the relative proportions of cations on the clay surfaces.

Of the common types of clay, montmorillonite has been observed to expand the most because it has the highest base exchange capacity. The effect is less prominent in soils with illite-vermiculite clay and even less prominent in kaolinite clays. Montmorillonite clays are known to exist throughout Santa Clara County soils. The coefficient of linear expansion, liquid limit, plasticity index, and percentage of montmorillonite by x-ray diffraction are measurable physical parameters of the soil that can be correlated to the potential change in hydraulic conductivity (Geologica, 2003).

The study also determined that recycled water irrigation could be used without adverse reaction at locations within Santa Clara County with low clay and/or low expansive clay content. Gypsum-treatment of soils can reduce the adverse impacts of recycled water on permeability. Similarly, recycled water sources can be treated with gypsum, sodium removal, or blending with other water sources to reduce the potential for affecting hydraulic conductivity (Geologica, 2003). However, this could potentially increase the transport of constituents of concern in groundwater.

In terms of water chemistry, the study found that recycled water had greater ion exchange of calcium and magnesium with the soils compared to other irrigation sources. The study concluded that additional testing is warranted to evaluate the impacts of recycled water on groundwater by focusing on ion exchange and percolating water chemistry. Additional hydraulic testing on a range of soils and waters can be used to determine the range of SAR and salinity that is safe from adverse impacts on permeability. It may also be important to evaluate what effect cycling between rainwater and recycled water due to seasonal changes will have on hydraulic conductivity (Geologica, 2003).

3.2. Other Plugging Mechanisms

3.2.1. Mineral Precipitation

Mineral precipitation depends on pH, temperature, and availability of large surface areas for precipitate deposition. Calcium carbonate, iron oxides, and manganese oxides are examples of insoluble compounds which may form. The ARWT Feasibility Project determined that mineral precipitation does not significantly alter hydraulic conductivity because precipitation kinetics are slow and it occurs in isolated pore spaces. In addition, the total volume of precipitation is not significant enough to change hydraulic conductivity (SCVWD, 2004). The correlation between expansive clay content of soils and change in hydraulic conductivity as a result of irrigation with recycled water also suggests that mineral precipitation in the short term is not a predominant process changing hydraulic conductivity in this situation (Geologica, 2003).

3.2.2. Physical Plugging

Physical plugging can be caused by accumulation of suspended solids from recycled water. Suspended solids can be inorganic such as silt, clay, fine sands, or flocs, or can be organic such as algal cells or decaying organic matter. The ARWT Feasibility Project determined based on past experiments that a total suspended solids (TSS) level less than 2,000 µg/L will not cause significant physical plugging. However, other research in the same aquifer system has shown that a level as high as 25,000 µg/L will not have adverse effects (SCVWD, 2004). Although the effect of the accumulation of solids may vary depending on soil permeability and porosity, it is most likely that the soil that is currently irrigated will be able to accommodate the range of suspended solids found in recycled water, as they are less than the range of storm water runoff which is mitigated by natural infiltration.

3.2.3. Biological Plugging

Biological plugging occurs due to in-situ bacterial growth. The accumulation of cells and waste products contribute to plugging of soil pores. The presence of biological contaminants in recycled water may contribute to this issue, but biological plugging can be effectively managed with disinfection of recycled water. The growth of biological material requires an energy and nutrient source. Growth is enhanced by warmer temperatures, sunlight, and greater concentrations of nutrients, of which at least the first two are not present in the subsurface (SCVWD, 2004).

3.3. Conclusions

Further investigation of soil aquifer plugging via clay expansion and dispersion is recommended. Recycled water with high SAR levels can affect the hydraulic conductivity of soil and hence the rate of percolation to groundwater resources. This effect is most commonly seen with soils that have high base exchange capacity like montmorillonite clays. Because Santa Clara County has such clays in its soil, aquifer plugging is a concern.

Further investigation of soil aquifer plugging due to mineral precipitation, physical plugging, and biological plugging is not recommended. These other mechanisms are not as likely to significantly affect groundwater resources.

4. MODELING TOOLS

The next phase of this project is the fate and transport evaluation, which will include use of a model to simulate the migration of recycled water constituents through the vadose zone. During the literature review, four of these analytical models were identified: PHREEQ, HYDRUS, MINTEQA2, and Soil Attenuation Model (SAM). The four modeling programs can potentially be used to characterize fate and transport of recycled water constituents.

4.1. PHREEQ

PHREEQ is a modeling program developed by USGS to characterize speciation, batch-reaction, one dimensional transport, and perform inverse geochemical calculations. PHREEQC is the latest version of PHREEQ written in the C programming language. PHREEQC is capable of performing a range of low-temperature aqueous geochemical calculations.

Version 2 of PHREEQC includes features for dispersion/diffusion and stagnant zones in one-dimensional transport calculations, kinetic reactions with user-defined rate expressions, formation/dissolution of ideal/multicomponent/nonideal binary solid solutions, fixed volume or fixed pressure phases, variation in the number of surface or exchange sites with the dissolution/precipitation of minerals or kinetic reactions, isotope mole balances in inverse modeling calculations, and multiple sets of convergence parameters. Version 2 also allows users to print user-defined quantities to a primary output file or to a spreadsheet-compatible file (USGS, 2005).

Advantages

Based on an ion-association aqueous model, PHREEQ is capable of speciation and saturation-index calculations. It can perform one-dimensional transport calculations involving reversible reactions. It can model transformation in the aqueous phase, gas phase, and solid-solution. The model can also address transformation involving mineral, surface-complexation, and ion-exchange equilibria. It can also account for irreversible reactions, which include specified mole transfers of reactants, kinetically controlled reactions, mixing of solutions, and temperature changes. In addition, it is capable of inverse modeling, which finds sets of mineral and gas mole transfers that account for differences in composition between waters, within specified compositional uncertainty limits (USGS, 2005).

Disadvantages

PHREEQ requires a lot of input data that is very specific to the soil type, including the concentrations of every ion present that may react with the water constituents. Since this information will be very location-specific, the model results may not be applicable over a larger area, such as the entire Santa Clara and Llagas Subbasins.

4.2. HYDRUS

HYDRUS is a finite element model that simulates movement of water, heat, and multiple solutes in a media that is variably saturated. The model was developed jointly by scientists at the University of California at Riverside and the Agricultural Research Service division of the US Department of Agriculture. HYDRUS-1D is a one-dimensional public domain version of the HYDRUS model. HYDRUS has also been developed in two- and three-dimensional versions. In HYDRUS-1D, the Richards equation is used for saturated-unsaturated water flow and the Fickian advection/dispersion equations are used for heat and solute transport (Šimunek et al., 2005b).

The program can account for unsaturated flow, water uptake and transpiration by plants, evaporation from soil surface, solute adsorption by the solid phase, and solute degradation. The current version 3.0 includes simulation of preferential flow of water and dissolved constituents through the unsaturated zone using a hierarchy of modules of increasing complexity. The modules account for the presence of immobile water, exchange of water or solutes between solid macropores and the soil matrix, and possible water flow and solute transport in both the macropores and micropores. Version 3.0 also includes options to simulate the transport of viruses, bacteria, and colloids in the soil. Simulation includes provisions for kinetic attachment/detachment of colloid or pathogens to the solid phase, physical straining of colloid particles by the solid phase, and possible accumulation at air-water interfaces when the soil becomes unsaturated (Šimunek et al., 2005a).

A review of three projects conducted by the Agricultural Research Service confirmed that HYDRUS is a valuable tool in for analyzing and designing irrigated agricultural systems. The three projects included in the review included analyzing drip irrigation systems, simulating the effects of salinity and drought stress on root water uptake, and using inverse modeling to assess upward water flow from shallow groundwater (Skaggs et al., 2005).

HYDRUS can also be coupled with other software packages. Šimunek et al. (2005) coupled HYDRUS to several other packages including UNSATCHEM, the PHREEQ biogeochemical code, and Constructed Wetlands 2D (CW2D). The coupled model of HYDRUS and UNSATCHEM has been used to make quantitative predictions on the effects of salinity on plant growth and the amount of water and amendment required to reclaim salt-affected soil profiles. HP1, a coupling of HYDRUS and PHREEQC, accounts for complexation, cation exchange, surface complexation, precipitation-dissolution and redox reactions. The combined model of CW2D and the two-dimensional version of HYDRUS characterizes biochemical transformation and degradation processes in subsurface flows in constructed wetlands and includes biochemical degradation and transformation process for organic matter, nitrogen, and phosphorus. Biochemical components in the CW2D program are dissolved oxygen, organic matter (readily biodegradable, slowly biodegradable, inert), nitrogen compounds (ammonium, nitrite, nitrate, dinitrogen), inorganic phosphorus, and microorganisms (heterotrophic, autotrophic). The model assumes that heterotrophic bacteria are responsible for hydrolysis, mineralization of organic matter and denitrification, and autotrophic bacteria are responsible for nitrification (Šimunek et al., 2005a).

The Agricultural Research Services recently performed a research project to improve HYDRUS by implementing new processes and by testing the software against experimental data. The project plan included improved capabilities for simulating 3D transport problems, preferential flow as modeled with alternative dual-permeability models, multicomponent solute transport as applied to toxic trace elements, energy balance at the soil service, overland flow to improve the design of surface irrigation systems, and colloid and colloid-facilitated transport.

Advantages

HYDRUS-1D is capable of one dimensional transport of multiple solutes. Transport equations can account for nonlinear and non equilibrium reactions between the solid and liquid phases, linear equilibrium reactions between the liquid and gaseous phases, zero order production, and two first-order degradation reactions: one which is independent of other solutes, and one which provides coupling between solutes involved in sequential first-order decay reactions. Also, HYDRUS-1D provides the option of choosing different methods to represent parts of the model.

Disadvantages

HYDRUS-1D does not directly consider geochemical reactions; however degradation rates can be input to represent geochemical transformations. HYDRUS-1D results may also be very sensitive to parameters which are variable across the entire Santa Clara and Llagas groundwater subbasins, such as soil characteristics.

4.3. MINTEQA2

MINTEQA2 is a model developed by USEPA for geochemical equilibrium speciation for dilute aqueous systems. Adsorption data are not included in the database as they are left to the user to select for each specific problem. Seven adsorption models are available to match the adsorption input data. An associated program called PRODEFA2 has been incorporated into MINTEQA2 to assist with creating the input files (USEPA, 1991).

A Windows-based implementation of MINTEQA2, Visual MINTEQ, is available for free download. Visual MINTEQ includes ion speciation using equilibrium constants, solubility calculations involving solid phases, adsorption calculations with adsorption isotherms, ion exchange calculations using the

Gaines-Thomas formalism, metal-humic complexation, calculations for redox couples and gases, sweep runs in which one parameter is varied, and titrations (KTH, 2007).

Advantages

The model is useful for characterizing equilibrium mass distribution for dissolved species, adsorbed species, and multiple solid phases. MINTEQA2 includes a comprehensive thermodynamic database of equilibrium constants which can be modified if data are incomplete or inadequate to a specific problem.

Disadvantages

MINTEQA2 does not model the transport of constituents, only physical and chemical equilibrium. Hence, it cannot be used to estimate transport of constituents to groundwater.

4.4. Soil Attenuation Model (SAM)

SAM provides conservative estimates soil to groundwater contaminant releases based on annual rainfall, soil type, depth to groundwater and hydrogeological properties.

Advantages

SAM is a very simple model to implement, requiring minimal data input compared to other models. SAM can predict the upperbound constituent concentrations in groundwater based on soil concentrations. It can also back-calculate a lower bound soil site specific target level based on the applicable risk-based screening level at the groundwater point of exposure. SAM can be used for porous media soils impacted by either organic or inorganic constituents, in the absence of mobile non-aqueous phase liquids (Connor et al., 1997).

Disadvantages

The lack of consideration for geochemical reactions makes SAM inaccurate for many constituents. Furthermore, in the base version of this model, volatilization and biodegradation processes are neglected for simplicity. As discussed in Section 2, there are several recycled water constituents where these processes are expected to have a significant effect.

4.5. Recommendations

Based on the advantages and disadvantages of each model, HYDRUS-1D is recommended as the most suitable model for soil attenuation modeling. HYDRUS-1D can model the transport of multiple solutes in one dimension. It can account for solute transformation in the solid-aqueous phase, gas-aqueous phase, zero and first order degradation. Although HYDRUS-1D does not account specifically for geochemical reactions, inputs for degradation rates can be used which will serve the purpose of this study. The issue of sensitivity to input parameters can be accounted for by testing the model using a range of potential inputs. For more detailed investigations, the 2D or 3D versions of HYDRUS could be implemented, but since this modeling is intended to apply generally to the entire Santa Clara and Llagas subbasins, the 1D version is more suitable.

The other models discussed above have significant drawbacks which make them less valuable for this study. SAM is not suitable for modeling because of the lack of attenuation mechanisms such as volatilization and biodegradation. MINTEQA is not suitable because it does not model solute transport. PHREEQ can account for multiple physical and chemical processes that affect solute transport, but the results cannot be applied to a large area, since the input data is very specific to soil characteristics which are variable across the study area.

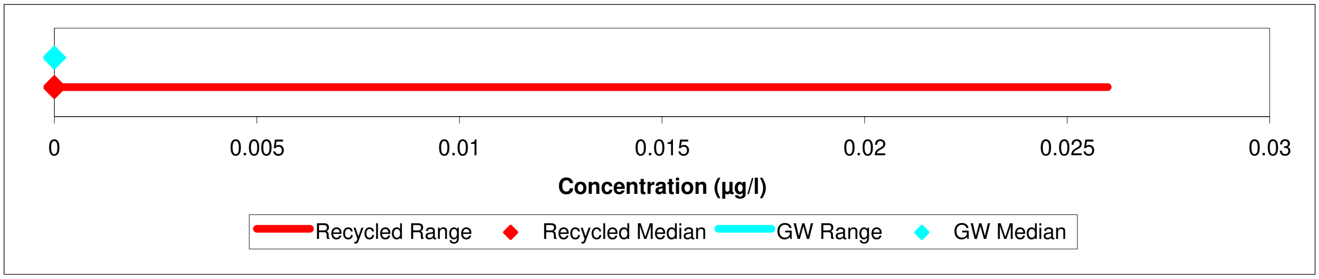
BOX PLOTS FOR GROUNDWATER AND RECLAIMED WATER CHEMISTRY

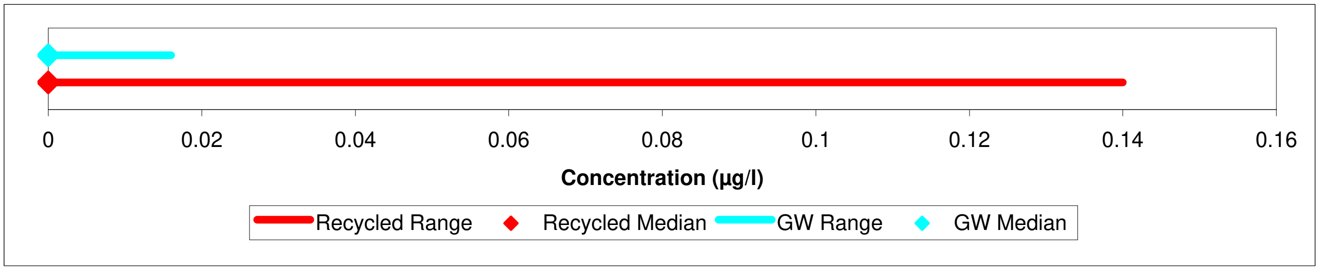
GROUNDWATER AND RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

AP/APEO, Halogenated



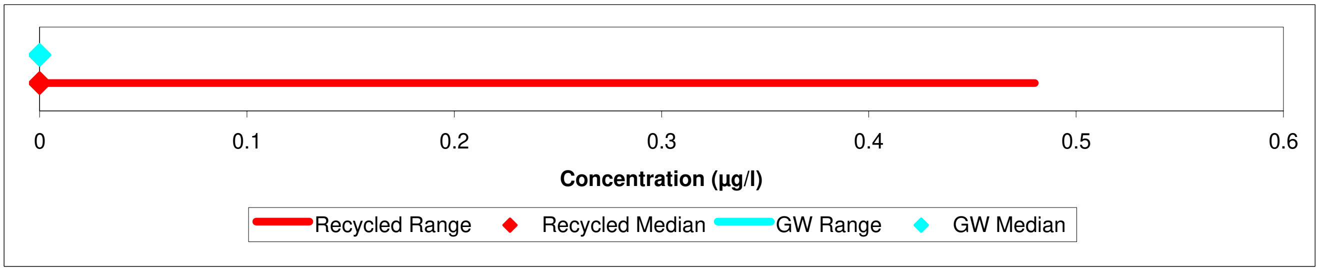
Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.026	Maximum: 0
Median: 0	Median: 0
Mean: 0.0027	Mean: 0
Count: 12	Count: 10
Detect Frequency: 17%	Detect Frequency: 0.0%

AP1EO



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.14	Maximum: 0.016
Median: 0	Median: 0
Mean: 0.0187	Mean: 0.001067
Count: 15	Count: 15
Detect Frequency: 13%	Detect Frequency: 6.7%

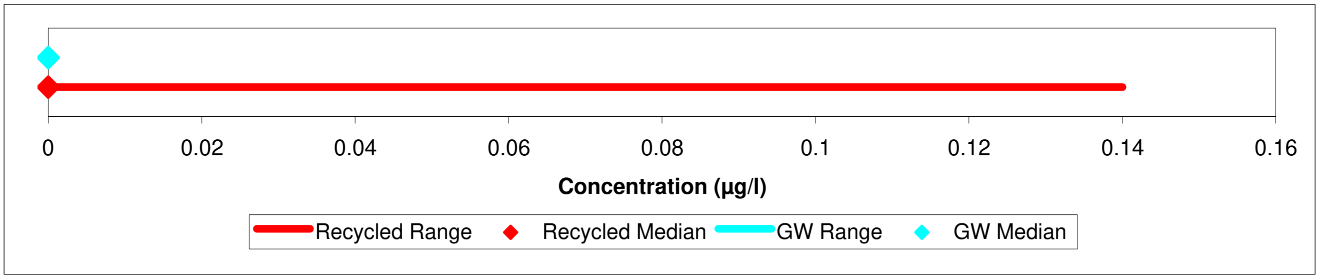
AP2EO



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.48	Maximum: 0
Median: 0	Median: 0
Mean: 0.048	Mean: 0
Count: 10	Count: 15
Detect Frequency: 10%	Detect Frequency: 0.0%

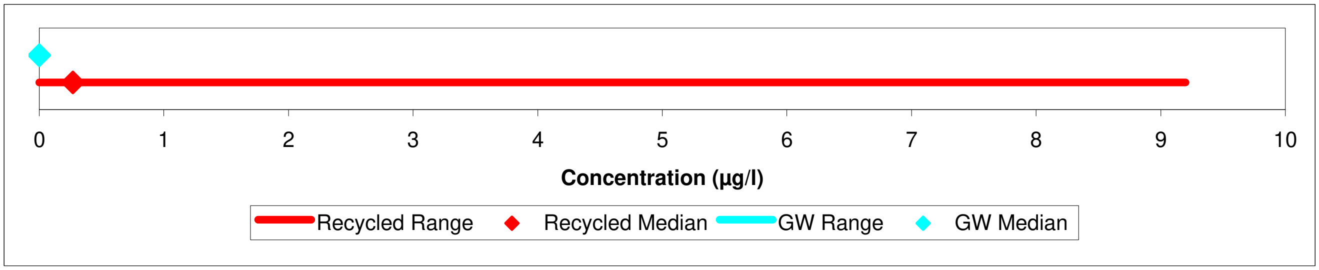
GROUNDWATER AND RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

AP3EO



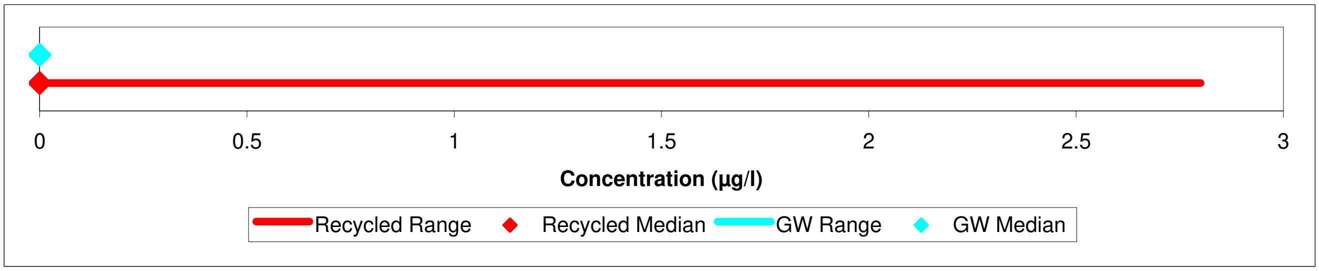
Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.14	Maximum: 0
Median: 0	Median: 0
Mean: 0.014	Mean: 0
Count: 10	Count: 15
Detect Frequency: 10%	Detect Frequency: 0.0%

APEC m/z 235



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 9.2	Maximum: 0.018
Median: 0.27	Median: 0
Mean: 2.044	Mean: 0.00253
Count: 10	Count: 15
Detect Frequency: 50%	Detect Frequency: 20.0%

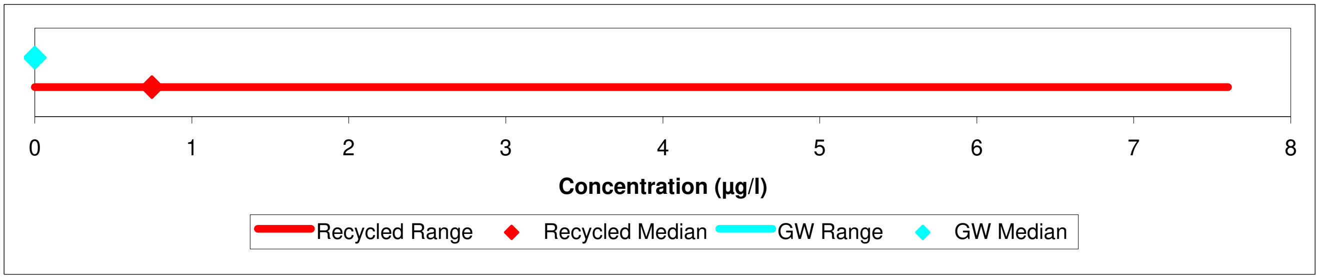
APEC m/z 249



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 2.8	Maximum: 0.014
Median: 0	Median: 0
Mean: 0.494	Mean: 0.002267
Count: 10	Count: 15
Detect Frequency: 40%	Detect Frequency: 40.0%

GROUNDWATER AND RECYCLED WATER CHEMISTRY SUMMARY STATISTICS

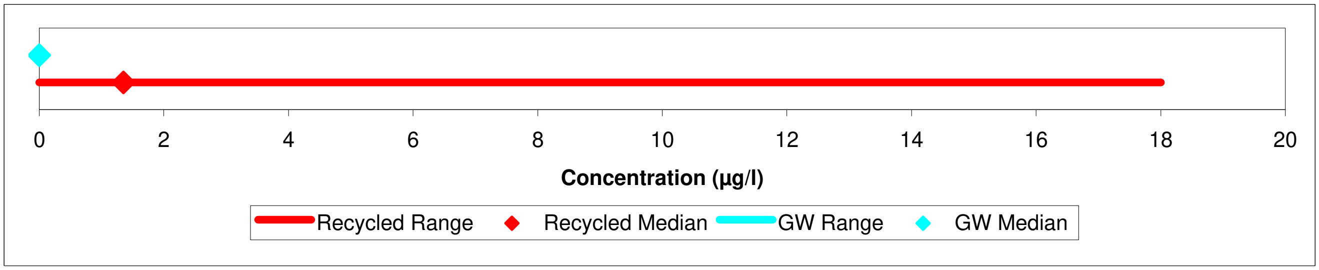
APEC m/z 279



Recycled Water
Minimum: 0
Maximum: 7.6
Median: 0.745
Mean: 1.952
Count: 10
Detect Frequency: 50%

Groundwater
Minimum: 0
Maximum: 0.019
Median: 0
Mean: 0.0024
Count: 15
Detect Frequency: 13.3%

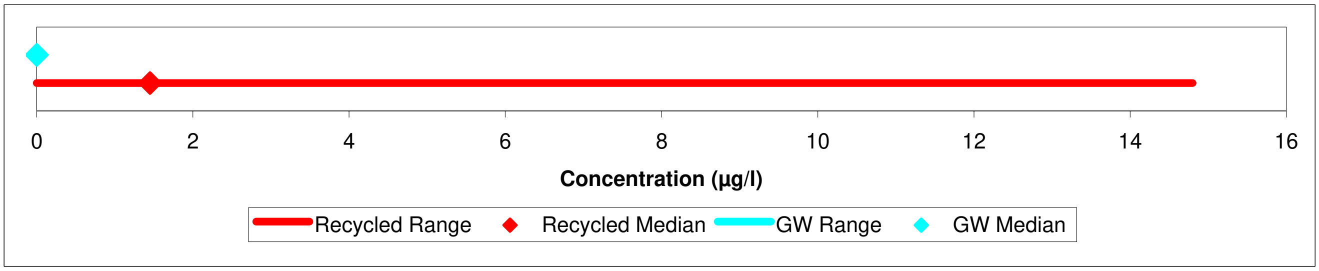
APEC Total



Recycled Water
Minimum: 0
Maximum: 18
Median: 1.35
Mean: 3.599
Count: 14
Detect Frequency: 64%

Groundwater
Minimum: 0
Maximum: 0.039
Median: 0
Mean: 0.0072
Count: 15
Detect Frequency: 40.0%

APEC, Halogenated

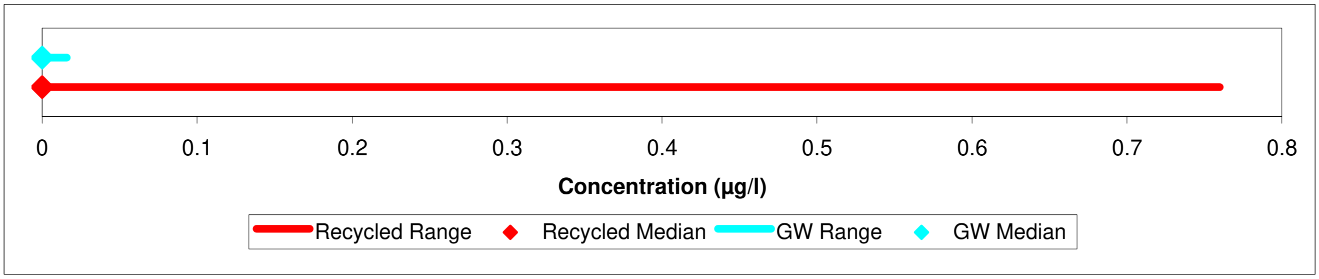


Recycled Water
Minimum: 0
Maximum: 14.8
Median: 1.45
Mean: 3.145
Count: 12
Detect Frequency: 92%

Groundwater
Minimum: 0
Maximum: 0
Median: 0
Mean: 0
Count: 10
Detect Frequency: 0.0%

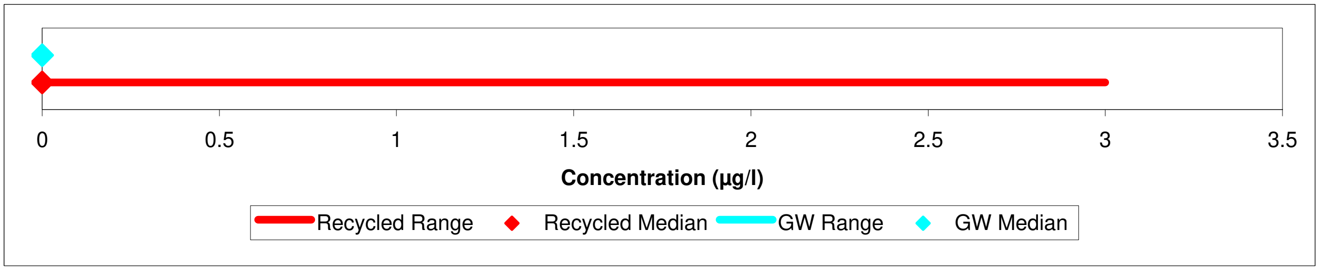
GROUNDWATER AND RECYCLED WATER CHEMISTRY SUMMARY STATISTICS

APEO Total



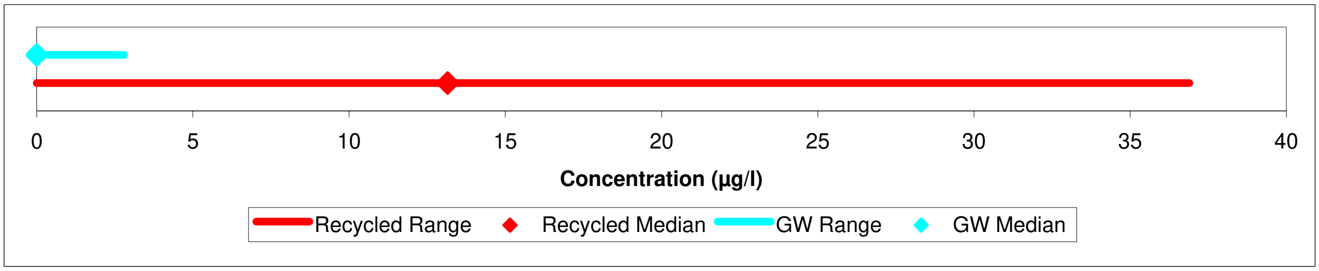
Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.76	Maximum: 0.016
Median: 0	Median: 0
Mean: 0.09	Mean: 0.001067
Count: 10	Count: 15
Detect Frequency: 20%	Detect Frequency: 6.7%

Bromate



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 3	Maximum: 0
Median: 0	Median: 0
Mean: 0.333	Mean: 0
Count: 18	Count: 19
Detect Frequency: 11%	Detect Frequency: 0.0%

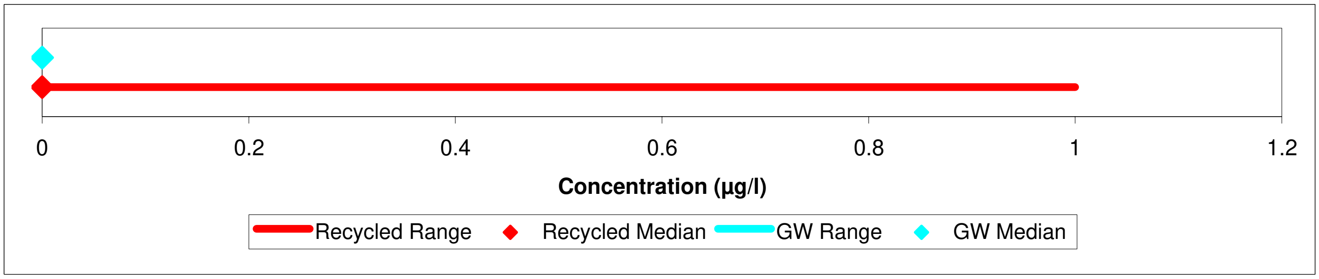
Bromochloroacetic Acid



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 36.9	Maximum: 2.8
Median: 13.15	Median: 0
Mean: 14.129	Mean: 0.6
Count: 14	Count: 9
Detect Frequency: 71%	Detect Frequency: 33.3%

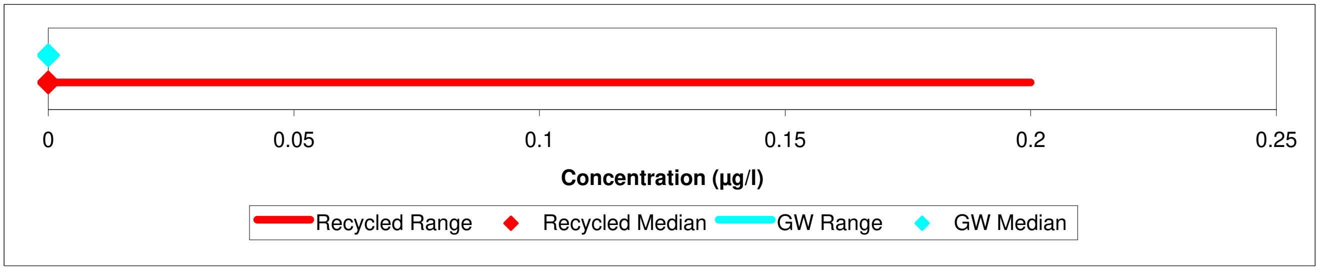
GROUNDWATER AND RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

Caffeine



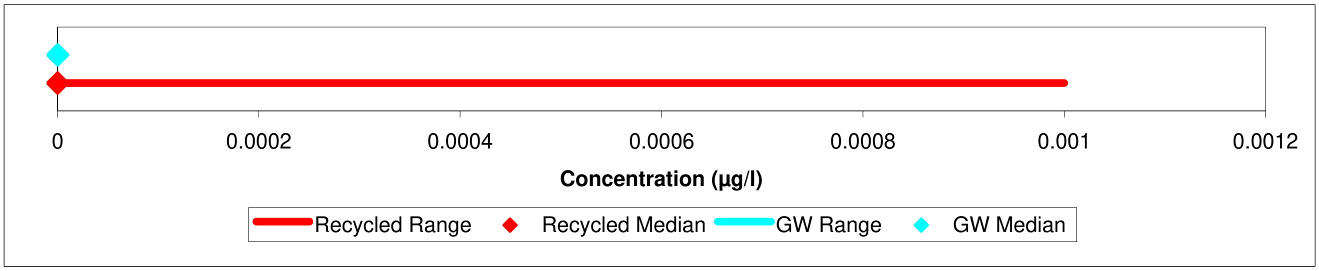
Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 1	Maximum: 0
Median: 0	Median: 0
Mean: 0.04	Mean: 0
Count: 25	Count: 18
Detect Frequency: 4%	Detect Frequency: 0.0%

Carbamazepine



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.2	Maximum: 0
Median: 0	Median: 0
Mean: 0.0167	Mean: 0
Count: 15	Count: 15
Detect Frequency: 13%	Detect Frequency: 0.0%

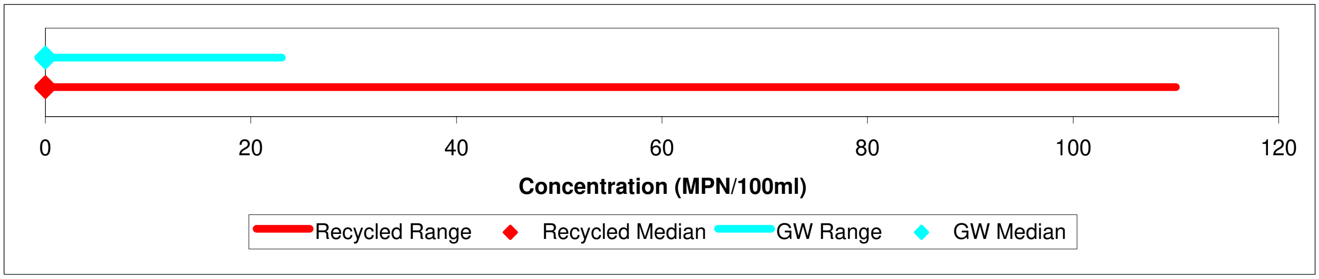
Carisoprodol



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.001	Maximum: 0
Median: 0	Median: 0
Mean: 0.00009	Mean: 0
Count: 11	Count: 10
Detect Frequency: 9%	Detect Frequency: 0.0%

GROUNDWATER AND RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

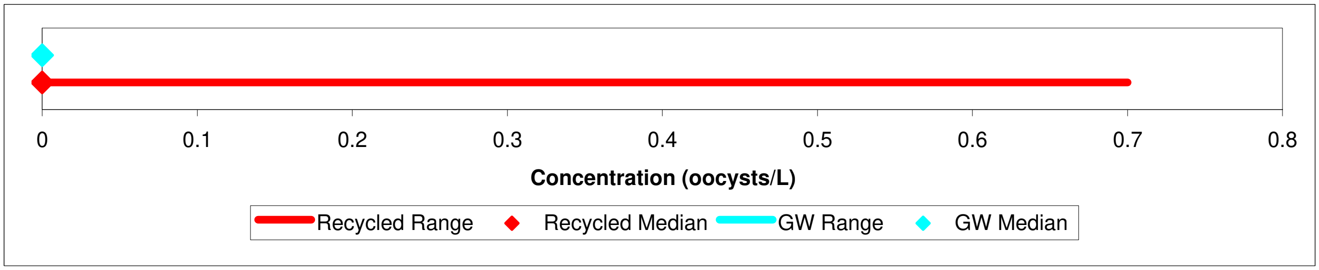
Coliforms, Total



Recycled Water
Minimum: 0
Maximum: 110
Median: 0
Mean: 8.056
Count: 18
Detect Frequency: 33%

Groundwater
Minimum: 0
Maximum: 23
Median: 0
Mean: 1.211
Count: 19
Detect Frequency: 5.3%

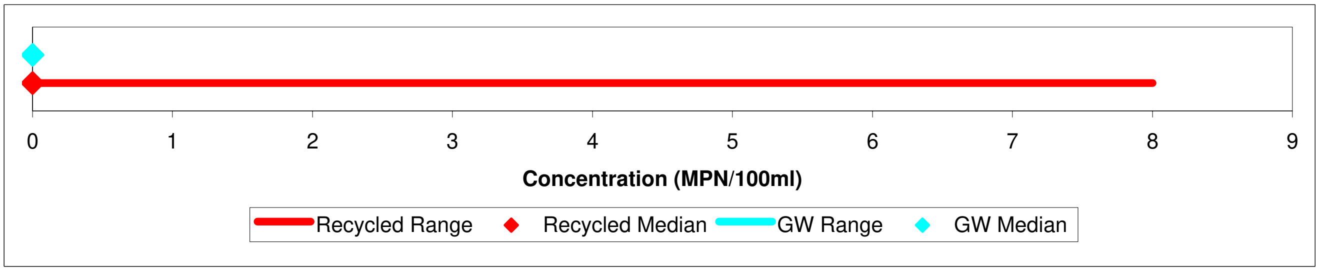
Cryptosporidium Oocysts



Recycled Water
Minimum: 0
Maximum: 0.7
Median: 0
Mean: 0.06
Count: 15
Detect Frequency: 13%

Groundwater
Minimum: 0
Maximum: 0
Median: 0
Mean: 0
Count: 20
Detect Frequency: 0.0%

E. Coli

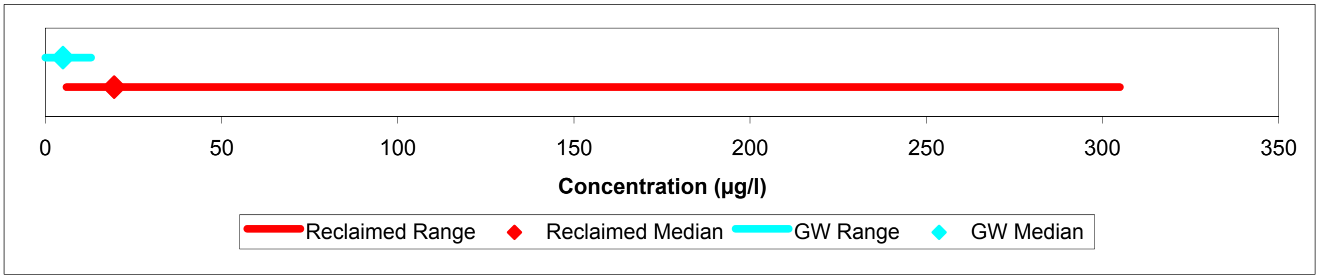


Recycled Water
Minimum: 0
Maximum: 8
Median: 0
Mean: 0.444
Count: 18
Detect Frequency: 6%

Groundwater
Minimum: 0
Maximum: 0
Median: 0
Mean: 0
Count: 5
Detect Frequency: 0.0%

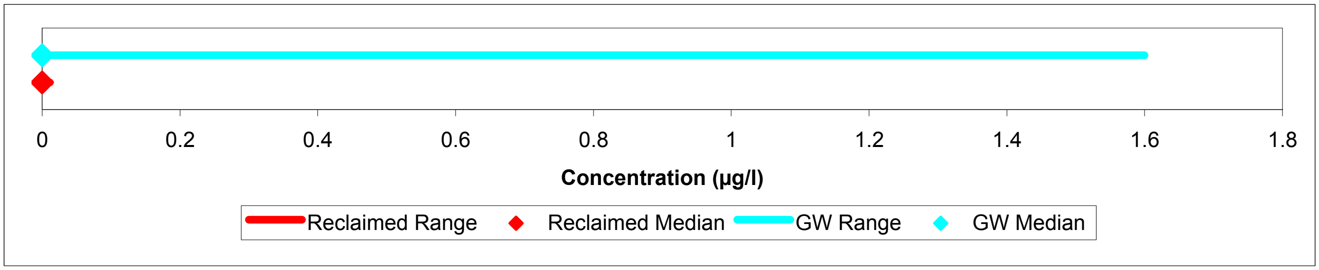
GROUNDWATER AND RECLAIMED WATER CHEMISTRY
SUMMARY STATISTICS

EDTA



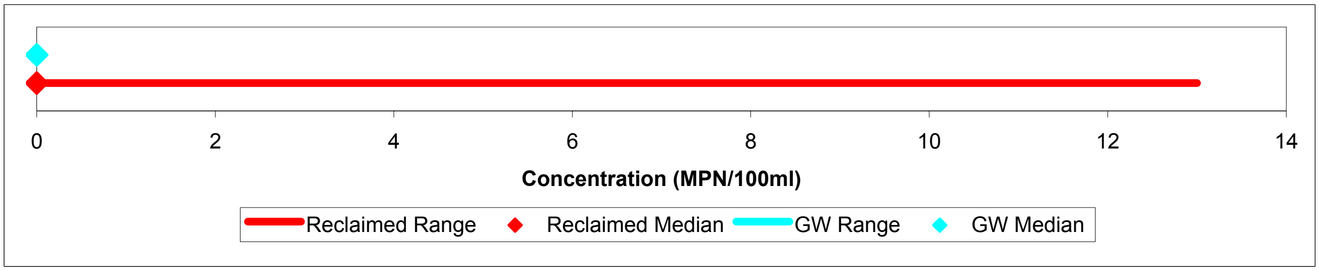
Reclaimed Water	Groundwater
Minimum: 6	Minimum: 0
Maximum: 305	Maximum: 13
Median: 19.5	Median: 5
Mean: 105.383	Mean: 4.736
Count: 6	Count: 11
Detect Frequency: 100%	Detect Frequency: 54.5%

Estrone



Reclaimed Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.011	Maximum: 1.6
Median: 0	Median: 0
Mean: 0.0006	Mean: 0.1067
Count: 18	Count: 15
Detect Frequency: 6%	Detect Frequency: 6.7%

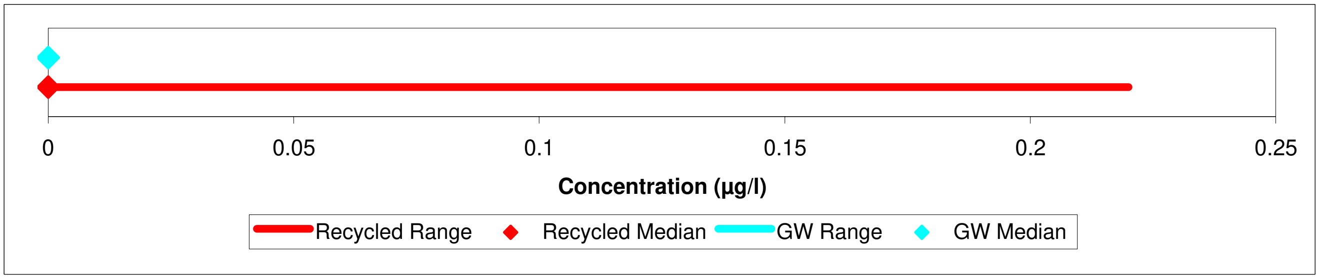
Fecal Coliforms



Reclaimed Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 13	Maximum: 0
Median: 0	Median: 0
Mean: 0.722	Mean: 0
Count: 18	Count: 5
Detect Frequency: 6%	Detect Frequency: 0.0%

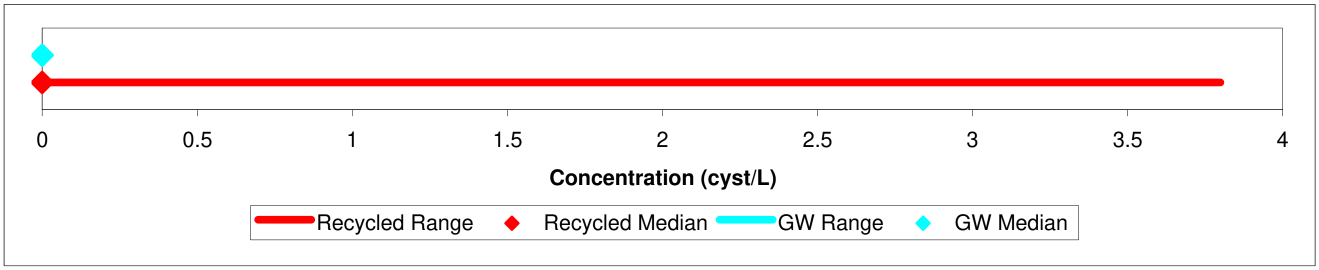
RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

Gemfibrozil



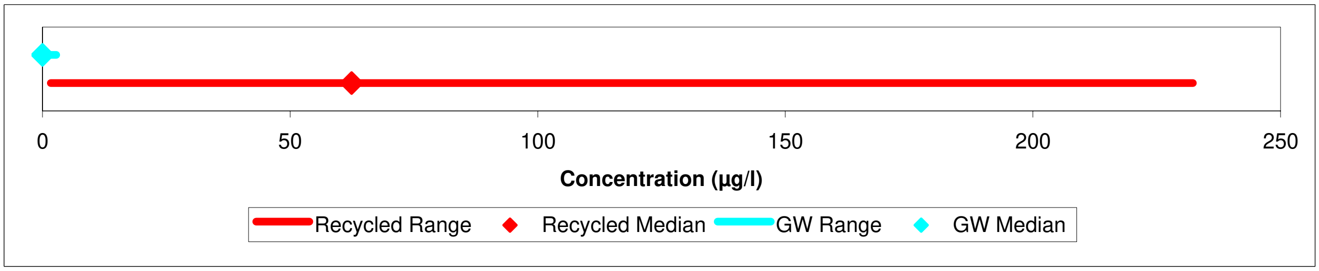
Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.22	Maximum: 0
Median: 0	Median: 0
Mean: 0.0167	Mean: 0
Count: 15	Count: 15
Detect Frequency: 13%	Detect Frequency: 0.0%

Giardia



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 3.8	Maximum: 0
Median: 0	Median: 0
Mean: 0.313	Mean: 0
Count: 15	Count: 20
Detect Frequency: 27%	Detect Frequency: 0.0%

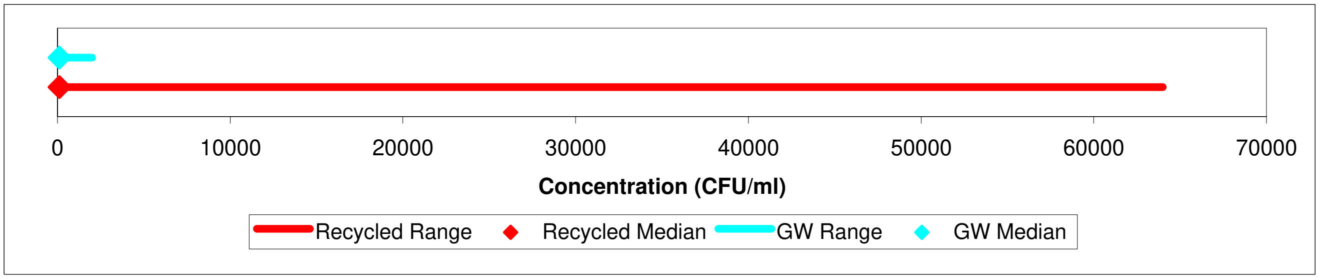
Haloacetic Acids (5)



Recycled Water	Groundwater
Minimum: 1.7	Minimum: 0
Maximum: 232.3	Maximum: 2.8
Median: 62.45	Median: 0
Mean: 83.361	Mean: 0.489
Count: 18	Count: 9
Detect Frequency: 100%	Detect Frequency: 22.2%

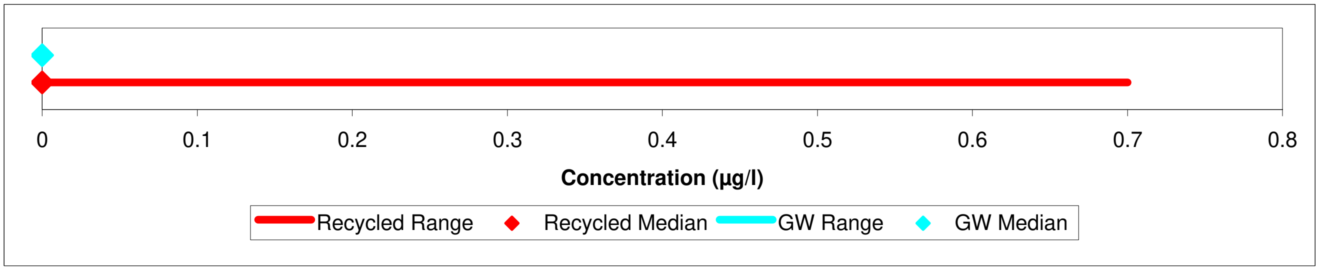
GROUNDWATER AND RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

Heterotrophic Plate Count by R2A



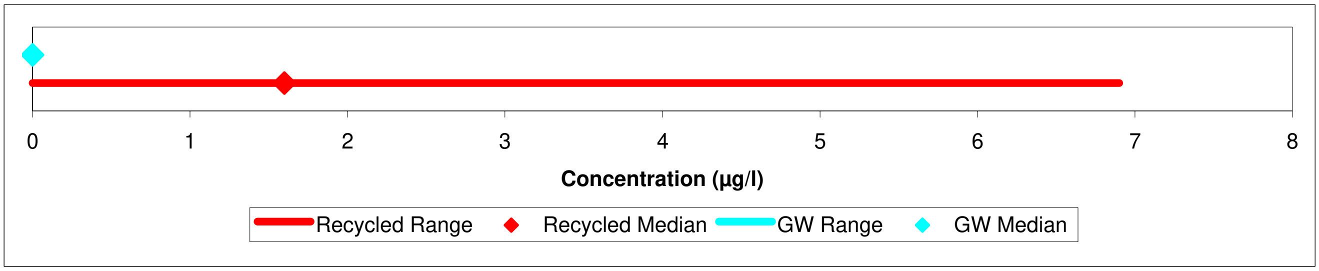
Recycled Water	Groundwater
Minimum: 0	Minimum: 2
Maximum: 64000	Maximum: 2000
Median: 117	Median: 110
Mean: 4770.61	Mean: 417.47
Count: 18	Count: 19
Detect Frequency: 83%	Detect Frequency: 100.0%

Ibuprofen



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 0.7	Maximum: 0
Median: 0	Median: 0
Mean: 0.0611	Mean: 0
Count: 15	Count: 15
Detect Frequency: 27%	Detect Frequency: 0.0%

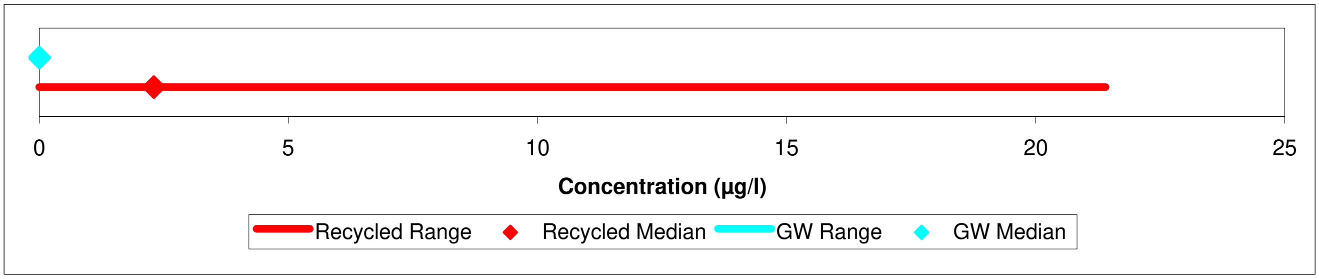
Monobromoacetic Acid



Recycled Water	Groundwater
Minimum: 0	Minimum: 0
Maximum: 6.9	Maximum: 0
Median: 1.6	Median: 0
Mean: 1.979	Mean: 0
Count: 19	Count: 9
Detect Frequency: 58%	Detect Frequency: 0.0%

GROUNDWATER AND RECYCLED WATER CHEMISTRY SUMMARY STATISTICS

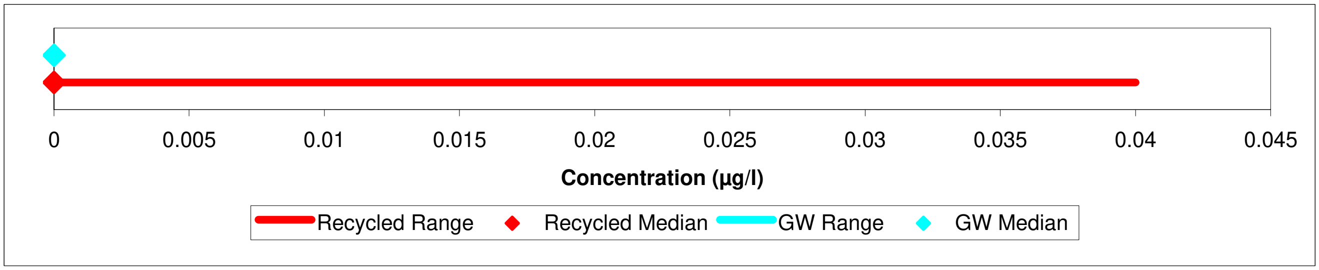
Monochloroacetic Acid



Recycled Water
Minimum: 0
Maximum: 21.4
Median: 2.3
Mean: 5.188
Count: 16
Detect Frequency: 63%

Groundwater
Minimum: 0
Maximum: 0
Median: 0
Mean: 0
Count: 9
Detect Frequency: 0.0%

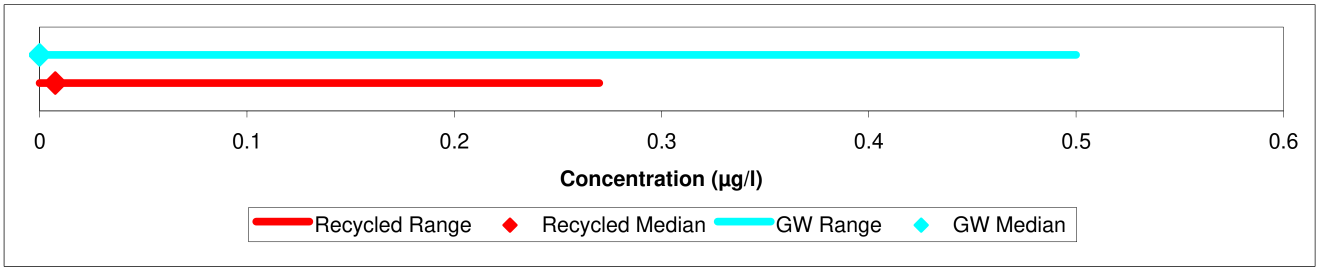
Naproxen



Recycled Water
Minimum: 0
Maximum: 0.04
Median: 0
Mean: 0.00267
Count: 15
Detect Frequency: 7%

Groundwater
Minimum: 0
Maximum: 0
Median: 0
Mean: 0
Count: 15
Detect Frequency: 0.0%

NBBS

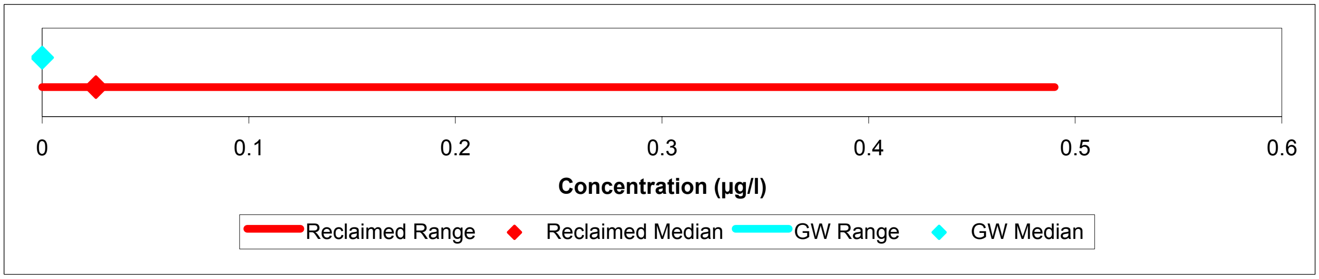


Recycled Water
Minimum: 0
Maximum: 0.27
Median: 0.0075
Mean: 0.0318
Count: 12
Detect Frequency: 67%

Groundwater
Minimum: 0
Maximum: 0.5
Median: 0
Mean: 0.05
Count: 10
Detect Frequency: 10.0%

GROUNDWATER AND RECLAIMED WATER CHEMISTRY
SUMMARY STATISTICS

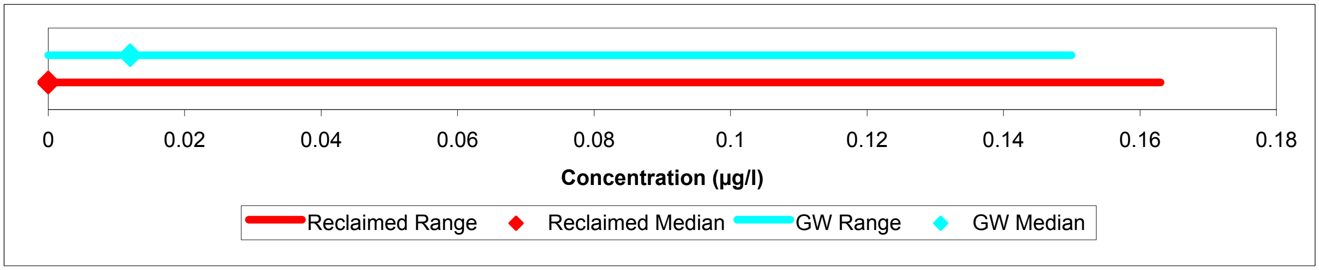
N-Nitroso dimethylamine (NDMA)



Reclaimed Water
Minimum: 0
Maximum: 0.49
Median: 0.026
Mean: 0.091453
Count: 15
Detect Frequency: 93%

Groundwater
Minimum: 0
Maximum: 0
Median: 0
Mean: 0
Count: 17
Detect Frequency: 0.0%

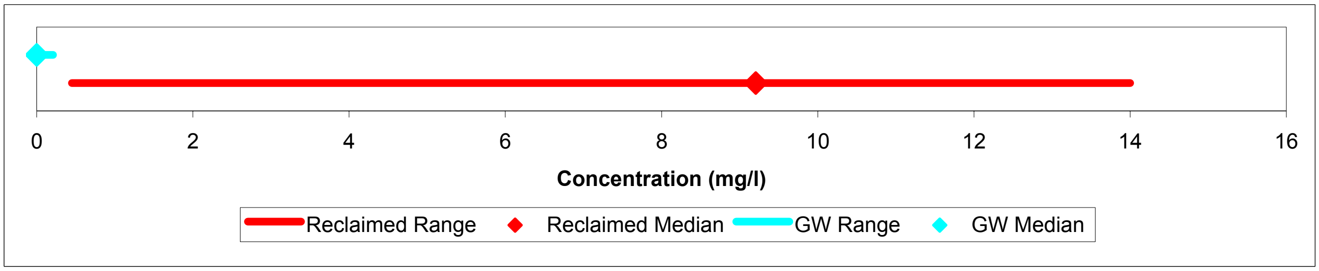
NP/OP



Reclaimed Water
Minimum: 0
Maximum: 0.163
Median: 0
Mean: 0.0272
Count: 15
Detect Frequency: 40%

Groundwater
Minimum: 0.012
Maximum: 0.15
Median: 0.012
Mean: 0.0323
Count: 15
Detect Frequency: 66.7%

Phosphate

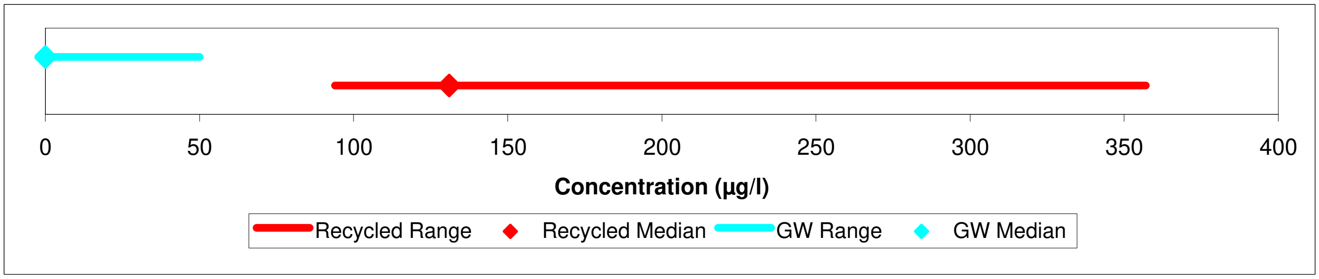


Reclaimed Water
Minimum: 0.45
Maximum: 14
Median: 9.205
Mean: 7.943
Count: 18
Detect Frequency: 100%

Groundwater
Minimum: 0
Maximum: 0.21
Median: 0
Mean: 0.0395
Count: 19
Detect Frequency: 36.8%

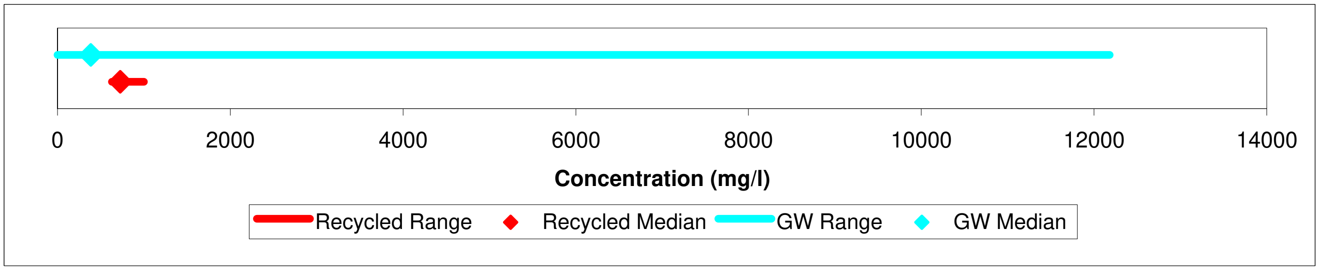
GROUNDWATER AND RECYCLED WATER CHEMISTRY
SUMMARY STATISTICS

Surfactants



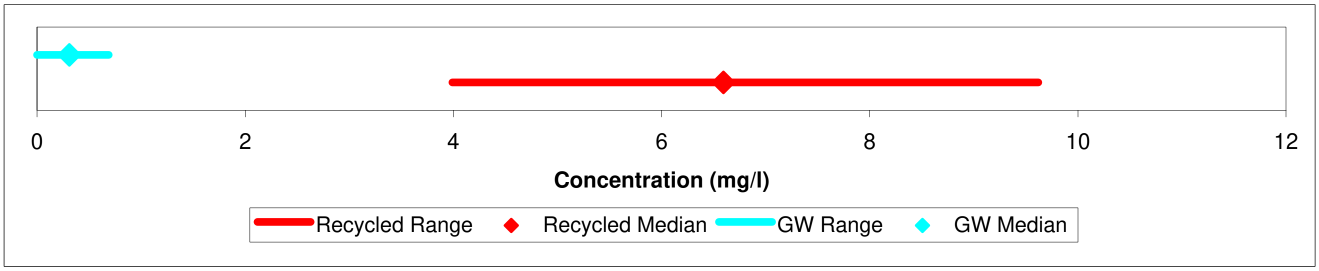
Recycled Water	Groundwater
Minimum: 94	Minimum: 0
Maximum: 357	Maximum: 50
Median: 131	Median: 0
Mean: 162	Mean: 0.0856536
Count: 14	Count: 2356
Detect Frequency: 100%	Detect Frequency: 7.3%

Total Filterable Residue at 180C (Total Dissolved Solids)



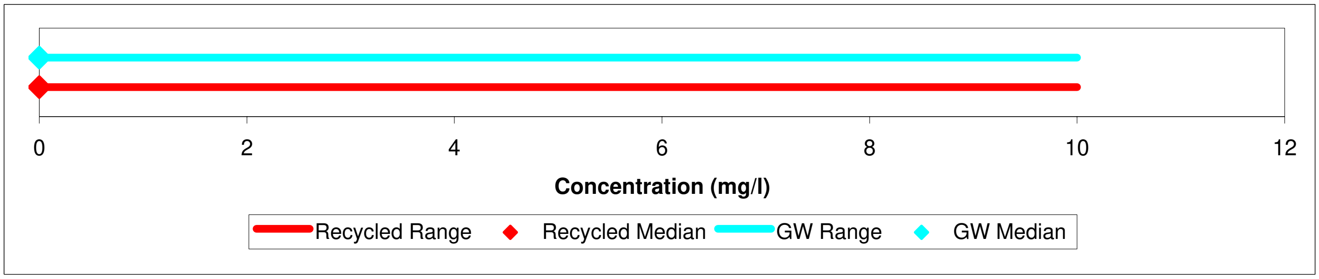
Recycled Water	Groundwater
Minimum: 630	Minimum: 0
Maximum: 1000	Maximum: 12180
Median: 724.5	Median: 384.5
Mean: 752.1	Mean: 456.59
Count: 20	Count: 3872
Detect Frequency: 100%	Detect Frequency: 99.9%

Total Organic Carbon



Recycled Water	Groundwater
Minimum: 3.99	Minimum: 0
Maximum: 9.62	Maximum: 0.69
Median: 6.595	Median: 0.31
Mean: 6.63	Mean: 0.319
Count: 18	Count: 19
Detect Frequency: 100%	Detect Frequency: 78.9%

Total Suspended Solids



Recycled Water
Minimum: 0
Maximum: 10
Median: 0
Mean: 2.167

TABLE I-2-1
LIST OF CHEMICALS ANALYZED IN RECYCLED WATER SAMPLES

Constituent	Data Presented in	Category
1,1,1,2-Tetrachloroethane	No detections, not plotted	
1,1,1-Trichloroethane	No detections, not plotted	
1,1,2,2-Tetrachloroethane	No detections, not plotted	
1,1,2-Trichloroethane	No detections, not plotted	
1,1-Dichloroethane	No detections, not plotted	
1,1-Dichloroethene	No detections, not plotted	
1,1-Dichloropropane	No detections, not plotted	
1,1-Dichloropropene	No detections, not plotted	
1,2,3-Trichlorobenzene	No detections, not plotted	
1,2,3-Trichloropropane	No detections, not plotted	
1,2,4-Trichlorobenzene	No detections, not plotted	
1,2,4-Trimethylbenzene	No detections, not plotted	
1,2-Dichlorobenzene	No detections, not plotted	
1,2-Dichloroethane	No detections, not plotted	
1,2-Dichloropropane	No detections, not plotted	
1,3,5-Trimethylbenzene	No detections, not plotted	
1,3-Dichlorobenzene	No detections, not plotted	
1,3-Dichloropropane	No detections, not plotted	
1,3-Dichloropropene	No detections, not plotted	
1,4-Dichlorobenzene	No detections, not plotted	
1,4-Dioxane	No detections, not plotted	
17β-Estradiol	No detections, not plotted	
2,2-Dichloropropane	No detections, not plotted	
2,3,7,8-TCDD	No detections, not plotted	
2,4,5-TP	No detections, not plotted	
2,4-D	No detections, not plotted	
2,4-Dinitrotoluene	No detections, not plotted	
2,6-Dinitrotoluene	No detections, not plotted	
2-Chlorotoluene	No detections, not plotted	
3-Hydroxycarbofuran	No detections, not plotted	
4,4'-DDD	No detections, not plotted	
4,4'-DDE	No detections, not plotted	
4,4'-DDT	No detections, not plotted	
4-Chlorotoluene	No detections, not plotted	
4-Isopropyltoluene	No detections, not plotted	
Acenaphthene	No detections, not plotted	
Acenaphthylene	No detections, not plotted	
Acetaminophen	No detections, not plotted	
Acetochlor	No detections, not plotted	
Aciflurfen	No detections, not plotted	
Alachlor	No detections, not plotted	
Aldicarb (Temik)	No detections, not plotted	
Aldicarb sulfone	No detections, not plotted	
Aldicarb sulfoxide	Appendix A	E
Aldrin	No detections, not plotted	
Alkalinity, Total	Appendix A	B
Alkylphenol Di-ethoxylate (AP2EO)	Appendix B	C
Alkylphenol Ethoxycarboxylate (APEC) m/z 235	Appendix B	C
Alkylphenol Ethoxycarboxylate (APEC) m/z 249	Appendix B	C
Alkylphenol Ethoxycarboxylate (APEC) m/z 279	Appendix B	C
Alkylphenol Ethoxycarboxylate (APEC), Halogenated	Appendix B	C
Alkylphenol Ethoxycarboxylate (APEC), Total	Appendix B	C
Alkylphenol ethoxylate (APEO), Total	Appendix B	C
Alkylphenol Mono-ethoxylate (AP1EO)	Appendix B	C
Alkylphenol Tri-ethoxylate (AP3EO)	Appendix B	C

TABLE I-2-1
LIST OF CHEMICALS ANALYZED IN RECYCLED WATER SAMPLES

Constituent	Data Presented in	Category
Alkylphenol/Alkylphenolethoxylates (AP/APEO), Halogenated	Appendix B	C
Alpha, Gross	Appendix A	D
Alpha-BHC	No detections, not plotted	
Alpha-chlordane	No detections, not plotted	
Aluminum	Appendix A	D
Anthracene	No detections, not plotted	
Antimony	No detections, not plotted	
Arsenic	No detections, not plotted	
Atrazine	No detections, not plotted	
Barium	No detections, not plotted	
Baygon (Propoxur)	No detections, not plotted	
Bentazon	No detections, not plotted	
Benz(a)Anthracene	No detections, not plotted	
Benzene	No detections, not plotted	
Benzo(a)pyrene	No detections, not plotted	
Benzo(b)Fluoranthene	No detections, not plotted	
Benzo(g,h,i)Perylene	No detections, not plotted	
Benzo(k)Fluoranthene	No detections, not plotted	
Beryllium	No detections, not plotted	
Beta, Gross	Appendix A	D
Beta-BHC	No detections, not plotted	
Bicarbonate Alkalinity	Appendix A	B
Bisphenol-A (BPA)	No detections, not plotted	
Boron	Appendix A	C
Bromacil	No detections, not plotted	
Bromate	Appendix B	D
Bromobenzene	No detections, not plotted	
Bromochloroacetic Acid	Appendix B	E
Bromochloromethane	No detections, not plotted	
Bromodichloromethane	Appendix A	C
Bromoform	Appendix A	C
Bromomethane	No detections, not plotted	
Butachlor	No detections, not plotted	
Butylbenzylphalate	No detections, not plotted	
Cadmium	Appendix A	D
Caffeine	Appendix B	E
Calcium	Appendix A	A
Carabaryl	No detections, not plotted	
Carbamazepine	Appendix B	E
Carbofuran (Furadan)	No detections, not plotted	
Carbon Tetrachloride	Appendix A	D
Carbonate Alkalinity	No detections, not plotted	
Carisoprodol	Appendix B	E
Chlordane	No detections, not plotted	
Chloride	Appendix A	A
Chlorine, Total	Appendix C	E
Chlorobenzene	No detections, not plotted	
Chlorobenzilate	No detections, not plotted	
Chloroethane	No detections, not plotted	
Chloroform	Appendix A	C
Chloromethane	No detections, not plotted	
Chloroneb	No detections, not plotted	
Chlorpyrifos (Dursban)	No detections, not plotted	
Chlorthalonil (Draconil, Bravo)	No detections, not plotted	
Chromium	No detections, not plotted	

TABLE I-2-1
LIST OF CHEMICALS ANALYZED IN RECYCLED WATER SAMPLES

Constituent	Data Presented in	Category
Chromium, Hexavalent	No detections, not plotted	
Chrysene	No detections, not plotted	
cis-1,2-Dichloroethene	No detections, not plotted	
cis-1,3-Dichloropropene	No detections, not plotted	
Clostridium Perfringens	No data, not tested for	E
Coliforms, Total	Appendix B	E
Conductivity	Not enough data, not plotted	
Copper	Appendix A	D
Cryptosporidium Oocysts	Appendix B	E
Cyanide	Appendix A	C
Dalapon	No detections, not plotted	
Delta-BHC	No detections, not plotted	
Di(2-ethylhexyl)adipate	No detections, not plotted	
Di(2-ethylhexyl)phthalate (DEHP)	Appendix A	D
Diazinon	No detections, not plotted	
Dibenz(a,h)Anthracene	No detections, not plotted	
Dibromoacetic Acid	Appendix A	E
Dibromochloromethane	Appendix A	C
Dibromochloropropane (DBCP)	No detections, not plotted	
Dibromomethane	No detections, not plotted	
Dicamba	No detections, not plotted	
Dichloroacetic Acid	Appendix A	E
Dichlorodifluoromethane	No detections, not plotted	
Dichlorovos (DDVP)	No detections, not plotted	
Dieldrin	No detections, not plotted	
Diethylphthalate	No detections, not plotted	
Diisopropyl Ether (DIPE)	No detections, not plotted	
Dimethoate	No detections, not plotted	
Dimethylphthalate	No detections, not plotted	
Di-N-Butylphthalate	No detections, not plotted	
Di-N-Octylphthalate	No detections, not plotted	
Dinoseb	No detections, not plotted	
Diquat	No detections, not plotted	
Dissolved Organic Carbon	Appendix C	A
Dissolved Oxygen	No data, not tested for	B
E. Coli	Appendix B	E
Endosulfan I (alpha)	No detections, not plotted	
Endosulfan II (beta)	No detections, not plotted	
Endosulfan sulfate	No detections, not plotted	
Endothall	No detections, not plotted	
Endrin	No detections, not plotted	
Endrin Aldehyde	No detections, not plotted	
Estradiol	No detections, not plotted	
Estriol	No detections, not plotted	
Estrone	Appendix B	D
Ethyl tert-Butyl Ether (ETBE)	No detections, not plotted	
Ethylbenzene	No detections, not plotted	
Ethylene Dibromide (EDB)	No detections, not plotted	
Ethylenediaminetetraacetic acid (EDTA)	Appendix B	C
Ethynylestradiol	No detections, not plotted	
Fecal Coliforms	Appendix B	E
Fluorene	No detections, not plotted	
Fluoride	Appendix A	D
Fluoroanthene	No detections, not plotted	
gamma-Chlordane	No detections, not plotted	

TABLE I-2-1
LIST OF CHEMICALS ANALYZED IN RECYCLED WATER SAMPLES

Constituent	Data Presented in	Category
Gemfibrozil	Appendix B	E
Giardia	Appendix B	E
Glyphosate	No detections, not plotted	
Haloacetic Acids (5), Total	Appendix B	E
Hardness	Appendix A	D
Heptachlor	No detections, not plotted	
Heptachlor Epoxide	Appendix A	D
Heptachlor Epoxide (isomer A)	No detections, not plotted	
Heptachlor Epoxide (isomer B)	No detections, not plotted	
Heterotrophic Plate Count	Appendix B	E
Hexachlorobenzene	No detections, not plotted	
Hexachlorobutadiene	No detections, not plotted	
Hexachlorocyclopentadiene	Appendix A	D
Hydroxide Alkalinity	No detections, not plotted	
Ibuprofen	Appendix B	E
Iminostilbene	No detections, not plotted	
Indeno(1,2,3,c,d)pyrene	No detections, not plotted	
Iron	Appendix A	D
Isophorone	No detections, not plotted	
Isopropylbenzene	No detections, not plotted	
Ketoprofen	No detections, not plotted	
Lead	Appendix A	D
Legionella Direct Isolation	No quantifiable results	
Lindane (gamma-BHC)	Appendix A	D
Magnesium	Appendix A	A
Malathion	No detections, not plotted	
Manganese	Appendix A	D
Medroxyprogesterone	No detections, not plotted	
Mercury	No detections, not plotted	
Methiocarb	No detections, not plotted	
Methomyl	No detections, not plotted	
Methoxychlor	No detections, not plotted	
Methyl Ethyl Ketone (MEK)	No detections, not plotted	
Methyl Isobutyl Ketone	No detections, not plotted	
Methyl tert-Butyl Ether (MTBE)	No detections, not plotted	
Methylene Chloride	No detections, not plotted	
Metolachlor	No detections, not plotted	
Metribuzin	No detections, not plotted	
Molinate	No detections, not plotted	
Monobromoacetic Acid	Appendix B	E
Monochloroacetic Acid	Appendix B	E
Naphthalene	No detections, not plotted	
Naphthalenedicarboxylic acids (NDCs)	No data, not tested for	E
Naproxen	Appendix B	E
N-Butyl Benzenesulfonamide (NBBS)	Appendix B	E
N-Butylbenzene	No detections, not plotted	
Nickel	Appendix A	D
Nitrate	Appendix A	C
Nitrilotriacetic acid (NTA)	No data, not tested for	C
Nitrite	Appendix A	C
Nitrobenzene	No detections, not plotted	
N-Nitroso Dimethylamine (NDMA)	Appendix B	C
Nonylphenol/Octylphenol (NP/OP)	Appendix B	C
ORP	No data, not tested for	B
Oxamyl (Vydate)	No detections, not plotted	

TABLE I-2-1
LIST OF CHEMICALS ANALYZED IN RECYCLED WATER SAMPLES

Constituent	Data Presented in	Category
Paraquat	No detections, not plotted	
Parathion	No detections, not plotted	
PCB 1016 Aroclor	No detections, not plotted	
PCB 1221 Aroclor	No detections, not plotted	
PCB 1232 Aroclor	No detections, not plotted	
PCB 1242 Aroclor	No detections, not plotted	
PCB 1248 Aroclor	No detections, not plotted	
PCB 1254 Aroclor	No detections, not plotted	
PCB 1260 Aroclor	No detections, not plotted	
PCBs, Total	No detections, not plotted	
Pendimethalin	No detections, not plotted	
Pentachlorophenol	No detections, not plotted	
Perchlorate	Appendix A	A
Perfluorochemicals	No data, not tested for	E
Permethrin (mixed isomers)	No detections, not plotted	
pH	Appendix A	B
Phenanthrene	No detections, not plotted	
Phosphate	Appendix B	C
Picloram	No detections, not plotted	
p-Isopropyltoluene	No detections, not plotted	
Primidone	No detections, not plotted	
Prometryn	No detections, not plotted	
Propachlor	No detections, not plotted	
Propanolol	No detections, not plotted	
Propylbenzene	No detections, not plotted	
Pyrene	No detections, not plotted	
Radium 226	No detections, not plotted	
Radium 228	Appendix A	D
Radon 222	No detections, not plotted	
sec-Butylbenzene	No detections, not plotted	
Selenium	No detections, not plotted	
S-Ethyl dipropylthiocarbamate (EPTC)	No detections, not plotted	
Silica	Appendix A	D
Silver	No detections, not plotted	
Simazine	No detections, not plotted	
Sodium	Appendix A	A
Strontium 90	No detections, not plotted	
Styrene	No detections, not plotted	
Sulfate	Appendix A	A
Surfactants	Appendix B	C
Terbacil	No detections, not plotted	
Terbuthylazine	Appendix C	C
tert-Amyl Methyl Ether (TAME)	No detections, not plotted	
tert-Butyl Alcohol	No detections, not plotted	
tert-Butylbenzene	No detections, not plotted	
Testosterone	No detections, not plotted	
Tetrachloroethene	No detections, not plotted	
Thallium	No detections, not plotted	
Thiobencarb	No detections, not plotted	
Toluene	No detections, not plotted	
Total Culturable Virus Assay	No detections, not plotted	
Total Filterable Residue at 180C (TDS)	Appendix B	A
Total Organic Carbon (TOC)	Appendix B	A
Total Suspended Solids (TSS)	Appendix B	D
Toxaphene	No detections, not plotted	

TABLE I-2-1
LIST OF CHEMICALS ANALYZED IN RECYCLED WATER SAMPLES

Constituent	Data Presented in	Category
trans-1,2-Dichloroethene	No detections, not plotted	
trans-1,3-Dichloropropene	No detections, not plotted	
trans-Nonachlor	No detections, not plotted	
Trichloroacetic Acid	Appendix A	E
Trichloroethene	No detections, not plotted	
Trichlorofluoroethane	No detections, not plotted	
Trichlorofluoromethane	No detections, not plotted	
Trifluralin	No detections, not plotted	
Trihalomethanes, Total	Appendix A, plotted individually	C
Tris(2,3-dichloropropyl)phosphate	Appendix B	E
Tris(3-chloropropyl)phosphate	Appendix B	E
Turbidity	Appendix A	D
Uranium	No detections, not plotted	
UV-254	Appendix B	A
Vinyl Chloride	No detections, not plotted	
Viruses	No detections, not plotted	D
Xylenes, Total	Appendix A	D
Zinc	Appendix A	D

Notes:
A - Significant Potential for Impact; Include for Monitoring
B - Important Parameter; Include for Monitoring
C - Inconclusive; Include for Monitoring
D - Minimum Potential for Impact; Omit from Monitoring
E - Insufficient Information; Include for Monitoring

EXECUTIVE SUMMARY

Volume II of this report is on the second phase of the Recycled Water Irrigation and Groundwater Study.The overall goal of the study is to evaluate the potential impact to groundwater from expanded use of recycled water for irrigation in the Santa Clara and Llagas Subbasins. The two main components that are focused in Volume II include soil attenuation modeling and bench test.

Soil Attenuation Modeling

This component of the study used a one-dimensional numerical model to estimate the transport of recycled water and its constituents from the surface to the groundwater. HYDRUS-1D was selected as the numerical model. Four recycled water constituents were modeled in HYDRUS-1D including bromodichloromethane, chloroform, m-xylene, and N-nitrosodimethylamine (NDMA). Each constituent was modeled in three different soil types (sand, silt, and clay) and over three time frames (2 months, 2 years, 50 years). The results of the soil attenuation model of the four constituents are presented in Figures II-1-1 to II-2-4.

The behavior of concentration curves of the modeled constituents was exponential in shape. Concentrations decreased with respect to depth and most of the initial attenuation occurred in the first several feet of soil. As time progressed, the constituents saturate along the depth similar to a wave front. Generally, clay had the highest attenuation capacity followed by silt and sand with the exception of NDMA. NDMA migration in the model was more prominent in the clays than silt or sand. This is because the increased percent saturation of the clay in the model allows less opportunity for volatilization of NDMA.

The main process in the model that contributes to attenuation is the high sorption onto soil particles. Adsorption capacity is fixed and over extended contact with recycled water constituents, that capacity may be spent. Degradation and transformation into daughter products were mechanisms that were not included in the model that may also contribute to attenuation.

A sensitivity analysis was performed to evaluate the sensitivity of the model's input parameters. The analysis determines the most important parameters that affect the model's outcome. Constituent characteristics including Henry's constant, adsorption isotherm, and the molecular diffusion in air are factors that most significantly determine the solute's potential for migration to groundwater. In addition, soil type plays an important role in determining which solutes present greater threats to groundwater. The factors that did not significantly change the model results were molecular diffusion in water, bulk density, and choice of transport model.

Soil Core Bench Test

The bench test was used to simulate the subsurface fate and transport of the recycled water under conditions similar to those expected on sites where recycled water would be used for irrigation. Eleven soil cores (1 foot in length for fine grained and 2.3 to 3.8 feet in length for semi-fine and coarse grained) were selected for the bench test from borings collected from the Santa Clara and Llagas Subbasins. The irrigation sources included in the test were recycled water from the San Jose/Santa Clara Water Pollution Control Plant (SJSC WPCP), and the South County Regional Water Authority (SCRWA) Gilroy Plant. Distilled water plus a calcium chloride additive was used as a control irrigation source. Gypsum was also included as a test parameter for fine grained soils to simulate common field practice to increase permeability. A depiction of the process flow is shown in Figure II-3-3.

Influents (the two recycled water sources and distilled water) and effluents were monitored twice. The first sampling event was at first breakthrough and the second sampling event was after ten pore volumes and was intended to be more representative of long term conditions. A list of the constituents that were monitored is listed in Table II-3-1.

Irrigation of cores for the bench test began on June 9, 2008, and continued through October 8, 2008. Of the eleven soil core sections, six had adequate effluent to complete the analysis of all constituents of concern shown in Table II-3-1. Due to extremely low permeability, the remaining soil core sections were unable to yield sufficient sample volume to analyze for all constituents.

Part of the evaluation included a characterization of the soil samples by conducting several tests as part of the bench test. Sieve analysis and hydrometer tests were completed to provide grain distribution information; hydraulic conductivity tests were completed to provide information about the soil permeability; and x-ray diffraction tests were performed to evaluate the clay mineralogy. Results for sieve analysis and hydrometer test, hydraulic conductivity, and x-ray diffraction for the soil samples are shown in Table II-3-2. Samples with low initial hydraulic conductivity (by ASTM D-5084, Method C) include SJSC-A SJSC-B, SCRWA-A, SCRWA-B, and SCRWA-D having a range of 10^{-8} to 10^{-5} centimeters per second (cm/sec). These soils cores all contain a high percentage of fine grains. Samples with high initial hydraulic conductivity (by ASTM D-5084, Method C) include SJSC-D, SCRWA-C, DI-A, DI-B, and DI-C having a range of 10^{-5} to 10^{-2} cm/sec. These soil samples tend to have higher coarse grain content, although DI-A and SJSC-D are outliers which have relatively high silt content and high initial hydraulic conductivity. Due to high rock content, there was not sufficient material to evaluate the SJSC-C soil sample for hydraulic conductivity.

The x-ray diffraction indicated that major clay minerals present in the soil samples include smectite, kaolinite, vermiculite, chlorite, and mica. Quartz, hydroxyl-interlayered 2:1, feldspar were found in lesser amounts. Due to the higher abundance of smectite in the samples collected from the Llagas Subbasin, more clay expansion is expected there, compared to the Santa Clara Subbasin. Given that gypsum use in conjunction with irrigation is a common best management practice, clay expansion is not expected to contribute to soil aquifer plugging. However, in cases where gypsum is not applied, significant clay expansion can occur, which could reduce infiltration rates and cause surface ponding.

The addition of gypsum had a significant effect in increasing the hydraulic conductivity of recycled water through fine grained soil. This is evident as the fine grained soil cores without gypsum (SJSC-A and SCRWA-A) produced very little effluent water. The respective fine grained soil cores with gypsum applied (SJSC-D and SCRWA-D) produced enough effluent water enough to complete the sampling objectives. Comparison of initial to final hydraulic conductivity values in soil cores SJSC-D and SCRWA-D shows that the increase in hydraulic conductivity when gypsum is applied can range from two to five orders of magnitude.

Bacterial growth was present in almost all the effluent samples as shown in the HPC results. Bacterial growth may have contributed to a lower hydraulic conductivity. However, since the majority of the effluents contained a high concentration of HPC, it is unknown what contribution bacterial growth had on soil aquifer plugging.

Chemical results are shown in Tables II-3-3 to II-3-11. Those results are also presented in Figures II-3-4 to II-3-48. The monitored constituents for the bench test can be grouped into categories based on their observed potential to migrate through the soil cores with minimal changes in concentration.

For purposes of this study, a significant change is regarded as a 20% change or more in concentration. Constituents that exhibited significant (20% or more) attenuation across the soil column for a majority of the soil cores include potassium, phosphate, nitrate, THMs, and some haloacetic acids (BCAA, DBAA, and DCAA). Constituents that exhibited consistent significant increases after percolation through soil include nitrite and PFCs.

Constituents that have exhibited initial large increases in the first round of sampling followed by no significant changes in the second round of sampling include DOC, TOC, calcium, and magnesium. The behavior of these constituents is suspected to be a result of an initial leaching from the soil cores, followed by equilibration with the infiltrating water.

Alkalinity, pH, TDS, DO, boron, chloride, sulfate and sodium exhibited no significant changes after percolation through soil. NDMA also does not appear to be affected by the transport through soil, although concentrations were variable from the influent to the effluent concentrations. One of the haloacetic acids (TCAA) and EDTA did not show strong removal.

Constituents that have been inconclusive due to significant variation in the influent concentration or high potential for bacterial growth include surfactants, HPC, and coliforms. Surfactant concentrations observed minor decreases in the SJSC soil cores, and minor increases in the SCRWA soil cores. Bromide, cyanide, terbuthylazine, NTA, E. Coli, and perchlorate were not detected in the influent or effluent samples.

Conclusions

The potential threat of each constituent to groundwater was categorized into low, medium and high threat categories based on the results of the bench test and modeling. A summary of those conclusions is provided in the table below.

Constituents	**High Risk**		**Medium Risk**	**Low Risk**		
	1) have shown an increase rather than a removal from soil percolation in the bench test	2) have not shown short-term significant removal and are not typically present in groundwater	1) have not attenuated from percolation in the bench test or model, and 2) are typically higher in recycled water than in groundwater	1) have exhibited significant attenuation in the bench test or model	2) have not exhibited significant attenuation but are similar in concentration in reclaimed water and groundwater	3) have not been detected in any of the samples in the bench test
Nitrite/Nitrate	X					
PFCs	X

Terbuthylazine						X
NTA						X

Constituents	**High Risk**		**Medium Risk**	**Low Risk**		
	1) have shown an increase rather than a removal from soil percolation in the bench test	2) have not shown short-term significant removal and are not typically present in groundwater	1) have not attenuated from percolation in the bench test or model, and 2) are typically higher in recycled water than in groundwater	1) have exhibited significant attenuation in the bench test or model	2) have not exhibited significant attenuation but are similar in concentration in reclaimed water and groundwater	3) have not been detected in any of the samples in the bench test
E. Coli						X
Perchlorate						X
other VOCs						X

Recommendations for the next phase of the study, the full-scale pilot study, include scaling back monitoring of low threat constituents. Monitored vadose zone wells should have shallow screens to monitor the depth range where a majority of the attenuation is expected to occur. The curvature of the concentrations along depth in the model indicates that the most drastic change in concentrations occurs in the first several feet of soil.

VOLUME II
SOIL ATTENUATION MODEL AND BENCH TEST
RECYCLED WATER STUDY

1. INTRODUCTION

1.1. Introduction

This report was prepared by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD) for the Recycled Water Irrigation and Groundwater Study. Volume II is the second phase of a study to evaluate the impacts from expanded use of recycled water for irrigation on groundwater resources in the Santa Clara and Llagas Groundwater Subbasins in Santa Clara County. This study uses a combination of approaches, including literature review, data analysis, a soil attenuation model, bench test, and a full pilot study at a site in the Santa Clara Groundwater Subbasin. This volume of the report will address the soil attenuation modeling and bench test. The next phase of the project is the full pilot study, the results of which are evaluated in conjunction with the conclusions gathered from the soil attenuation modeling and bench test.

1.2. Purpose

Volume II reports the results from two major evaluations: soil attenuation modeling and a soil core bench test. The purpose of the soil attenuation modeling is to use a numerical model (HYDRUS-1D) to estimate the transport of recycled water and the attenuation of its constituents from the surface to the groundwater. For this report, attenuation is defined as the reduction in concentration of a constituent through the soil, through any process such as sorption, volatilization, or degradation. Constituent migration is defined as the travel and rate of travel downward. Use of the model helps to evaluate potential impacts to groundwater from irrigation with recycled water under a wider range of variables than can be represented by the bench test or pilot study. The modeling results are also used to design the soil bench test and the following phase of this study, a full-scale pilot study using recycled water for irrigation. The goals for the soil attenuation model were identified as the following:

- Identify the range of attenuation from recycled water constituents with the greatest potential impacts to groundwater per the literature review;
- Investigate the effects of attenuation from different soil types (sand, silt, and clay);
- Determine the level of constituent attenuation with respect to depth and time; and
- Determine the sensitivity of the input parameters used in the modeling.

A soil core bench test is the second major component of the fate and transport evaluation. The bench test functions as a controlled environment for observing recycled water migration through soil samples. The purpose of the bench test is to characterize the attenuation of recycled water constituents through the soil, and also the effect of recycled water on the hydraulic conductivity of soil. To adequately represent the range of conditions observed within the project study area, the bench test used recycled water obtained from SJ/SC WPCP and SCRWA, and soil cores collected from multiple locations within the Santa Clara and Llagas Subbasins. The following goals were identified for the bench test:

- Determine the rate at which recycled water permeates through the varying soil samples relative to a control water source;
- Quantify the effects on soil hydraulic conductivity due to use of recycled water on a range of soils found within the project study area;
- Quantify the amount of attenuation through soil for a list of constituents present in recycled water that may negatively impact groundwater as determined Volume I of this report.

2. SOIL ATTENUATION MODEL

Recycled water commonly contains a number of constituents introduced through the original use of the water, or through the treatment processes that the water undergoes after use. The main focus of the study is chemical constituents, including those of anthropogenic and nonanthropogenic origins. A few constituents of concern are biological. The major goal of this study is to determine whether any of these constituents have the potential to negatively impact groundwater if recycled water is used for irrigation. In this section, the soil attenuation modeling and its application to this project are discussed.

2.1. Introduction

The goal of the attenuation model is to be able to characterize the fate and transport of the recycled water constituents through soil from the surface to groundwater. Four models were reviewed for this task, as discussed in Volume I of this report. Of the four models, HYDRUS-1D was chosen as the most suitable program, for its ability as a finite element model to simulate the movement of water and multiple constituents in a media that is variably saturated. For this task, a one dimensional (1D) model was chosen over a two or three dimensional model, because the model is intended to be representative of the entire project study area. 2D or 3D models for water infiltration would require customization for specific areas within the project study area and therefore the results would be less applicable to the entire area.

HYDRUS-1D is a one-dimensional public domain program. The model was developed jointly by scientists at the University of California at Riverside and the Agricultural Research Service division of the US Department of Agriculture. In HYDRUS-1D, the Richards equation is used for saturated-unsaturated water flow and the Fickian advection/dispersion equations are used for heat and constituent transport (Šimunek et al., 2005b).

2.2. Inputs

HYDRUS-1D requires representative input information for the model to adequately represent infiltration through the vadose zone. The input parameters include the soil depth and the time frame for which the model is run, the soil and constituent properties, and the water flow and constituent boundary conditions. Below is a further discussion of the input parameters.

2.2.1. Geometry and Time Information

A depth of 50 feet (15 meters) is selected for the model. Depth to first groundwater in the Santa Clara Subbasin ranges from 0 to more than 100 feet below ground surface (bgs). In the Llagas Subbasin, the depth to shallow groundwater varies from 10 to 100 feet bgs in the northeast region of the basin to less than five feet bgs near the Pajaro River. Because the model output reports a profile of concentrations at multiple depths, the concentration at any specific depth can be obtained by looking at specific points on the profile. Therefore, the model results are applicable for any depth to groundwater up to 50 feet. Since nearly all of the attenuation occurs within the upper few feet of the vadose zone, this scale was most appropriate for displaying the concentration changes over depth.

To evaluate the changes in recycled water infiltration over time, the time frame for the model was set from 0 to 50 years after commencement of application of recycled water. Snapshots of the model are taken at 2 months, 2 years, and 50 years to represent conditions at short, intermediate, and long time frames, respectively. The intermediate time step duration is similar to that of the pilot study, the next phase of the recycled water study and 2 months is the approximate duration between sampling events for the pilot study. Although in the real world, it is not absolutely certain that equilibrium will be established in the 50-year time frame, it is meant to represent the long term condition and is a best practical estimate. Soil parameters, recycled water application rate, and recycled water constituent concentrations are all assumed to be constant over the 50-year period.

2.2.2. Soil Hydraulic Model

For the soil hydraulics, the van Genuchten–Mualem equations are used. These equations for the hydraulic properties utilize the combination of the Mualem (1976) pore-size distribution model with the Van Genuchten (1980) soil-water-retention model. The model predicts the unsaturated hydraulic conductivity based on the water retention parameters. In addition, the model was assumed to have no hysteresis (no effects from wetting/drying cycles) as continuous irrigation is assumed in the modeling time frame. This assumption is a conservative estimate because irrigation with recycled water is not applied continuously through the day or during the seasonally wet months. Including the cyclic behavior of irrigation would introduce an additional widely variable parameter, and would reduce the interpretability of the results for the study area as a whole. The effect of the selection of this water transport model is evaluated in Section 2.4.3 below.

2.2.3. Constituent Transport

The Crank-Nicholson implicit scheme is applied to the model for time weighting. The Crank-Nicholson implicit scheme is recommended by the HYDRUS 1-D model documentation in lieu of other schemes. Although the fully implicit scheme may result in excessive numerical dispersion, explicit schemes are prone to numerical instabilities.

For space weighting, the method by Galerkin finite elements is used for approximating the spatial derivatives. This is the recommended space weighting method in the model.

Tortuosity in the molecular diffusion is accounted for by the model. Due to the presence of solid particles in the soil, diffusion paths do not keep straight lines. The tortuosity factor is applied for the molecular diffusion coefficients in the water and gas phases in accordance to Millington and Quirk (1961).

2.2.4. Soil Parameters

The model can be used for several types of soils. The examined soil types were sand, silt, and clay, which are taken to represent the range of vadose zone soils. Separate model scenarios were established for each of the soil types. Multiple layers of different soil types can be created in the model, but the model was simplified so that entire soil depth was one homogeneous type of soil. This provides a more general idea of the fate and transport through different soil types. In addition, a separate scenario was developed for the sensitivity analysis to observe the impact of heterogeneity of different soils on the model results.

Default soil properties included within the HYDRUS-1D model were used for each soil type. Soil property inputs include the residual soil water content, the saturated soil water content, saturated hydraulic conductivity, and the tortuosity.

Soil specific parameters include the bulk density and the longitudinal dispersivity. HYDRUS-1D recommends values for these parameters which are 94 pounds per cubic foot (pcf) (1,500,000 g/m^3) and 0.33 ft (0.1 meters), respectively. These values are typical for most soils and are not expected to vary significantly within the project study area. It is assumed that all sorption sites in the soil are in contact with the mobile water. It is also assumed that water transport is in physical equilibrium meaning that there is not any stagnant water in the soil column.

The model assumes the temperature of the environment to be 20 degrees Celsius throughout the depth of soil column. The temperature remains constant over time.

2.2.5. Constituent Parameters

Constituent specific parameters include the molecular weight, adsorption isotherm coefficient (K_d), Henry’s constant, and diffusion coefficients for free water and gas phase. Values for these parameters are available for some, but not all constituents of concern for this recycled water study. Therefore a subset of constituents with available data on their properties was selected for modeling. Sensitivity analysis on constituent parameters was performed (Section 2.4) to evaluate constituents for which these values are not available. The sensitivity analysis broadens the applicability of this model for other constituents.

Values of the adsorption isotherm coefficient (K_d), Henry’s constant, and diffusion coefficients were obtained through published values (Schwarzenbach et al, 2003; Alabama Dept of Env. Mgmt, 2008). Values of these parameters are shown in Table II-1-1.

To provide some range in chemical properties, four constituents were used for this model: bromodichloromethane, chloroform, m-xylene, and N-nitrosodimethylamine (NDMA). Bromodichloromethane and chloroform are disinfection by-products produced when water that contains organic matter is disinfected with chlorine or bromine. M-xylene is a one of three xylene isomers (m-xylene, p-xylene, and o-xylene). Xylenes are predominantly used as a solvent. NDMA is another disinfection by-product formed from the presence of monochloramine and simples amines. NDMA is frequently detected in municipal sewage and may be formed during wastewater disinfection when chlorine is applied in the presence of ammonia. The selection of these constituents for modeling was based on their presence in recycled water and the availability of information on their chemical properties. NDMA is frequently detected in recycled water. Bromodichloromethane, chloroform, and xylenes are less frequently detected in recycled water as explained in Volume I; however, the availability of the constituents' specific chemical characteristics made them appropriate selections for this evaluation. Further background discussion of these constituents may be found in Volume I of this report. HYDRUS-1D does not have the capability to model precipitation and dissolution reactions or constituent degradation in a manner that cannot be represented by first-order or second-order kinetics. Therefore, constituents with these characteristics (e.g. groundwater ions) cannot be modeled adequately using HYDRUS-1D.

While there is the potential for degradation of the constituents and/or transformation into daughter products, the model assumes that these processes are not occurring. The assumption is conservative for the constituents in recycled water.

2.2.6. Boundary Conditions

The upper boundary condition for water flow is set at a prescribed constant pressure head. The initial pressure head is -328 ft (-100 meters) to represent a soil that is unsaturated (pressure head below the bottom of the soil column). The lower boundary condition of the water flow is modeled as free drainage. Using this condition, any infiltrating water that migrates to the bottom of the modeled soil section flows into the groundwater. This condition is appropriate for a water table below the area of interest. For simplicity, the boundary conditions set for water flow are constant for the duration of the model. Considering the climate of the San Francisco Bay area, the seasonal weather patterns would expose the surface to higher volumes of water during short winter storm events in addition to routine irrigation water during the winter months. However, over the time periods used for this model, this fluctuation would be secondary to the water flow from irrigation.

Upper and lower boundary conditions of the constituent concentration are set at 100 mg/L as the concentration of the constituent in recycled water at irrigation and zero gradient (free drainage) at the end of the soil column. The concentration of the upper boundary condition is arbitrary as the model has been set to assume no degradation. In HYDRUS-1D, the transport factors are not dependent on concentration, except for degradation which is not included in this analysis. Hence, the model behavior is not affected by the actual concentration amount. For ease of interpretation, the concentration in the irrigation water was set at 100 mg/L, and therefore any concentrations modeled along the depth of the soil profile are effectively a percentage of the initial concentration in the irrigation water.

2.2.7. Root Water Uptake

The root water uptake was modeled using the Feddes (1977) water uptake reduction model. Under root water uptake the constituent is assumed to be left behind in the soil and only constituent-free solution is taken up to the roots. This assumption is valid because the modeled constituents are not known to be taken up by the plant root pathway. Root water uptake is modeled using Feddes' parameters for grass.

2.3. Results

Graphs showing the four constituent concentration profiles with respect to depth are presented in Figures II-1-1 to II-2-4. Each figure presents three concentration curves for the three time frames: 2 months, 2 years, and 50 years. For each of the four constituents modeled, three separate figures are presented that correspond to concentration curves in the three soil types modeled (sand, silt, and clay).

The concentration curves of the constituents may underestimate the actual attenuation, because constituent degradation and transformation were not included in the model. However, these factors are expected to be minimal for the selected constituents. The main process controlling the attenuation in the model is sorption to the soil particles. Because soil sorption is a process that becomes less effective over time as the soil becomes saturated with the constituent, it is expected that the constituent concentrations in the subsurface would eventually become consistent with the irrigated concentration over the long-term time frame. Clay appears to have the highest attenuation capacity except in the case of NDMA. Additional explanation for the modeled NDMA behavior is discussed in Section 2.3.4.

The curvature of the concentration profiles does not differ significantly between constituents. Each constituent has similar behavior with respect to the concentration profile and the progression of the concentration over time. NDMA appears to show the most attenuation of the evaluated constituents in sand and silt. In clay soils, m-xylene showed the most attenuation. These observations are reflective of the constituents' adsorption isotherm coefficients which govern the equilibrium of the constituent in soil and water. Of the four constituents, m-xylene has the highest adsorption isotherm coefficient. Transport behavior of the individual constituents is discussed below.

2.3.1. Bromodichloromethane

Bromodichloromethane concentration to depth curves are shown in Figures II-2-1A to II-2-1C. Bromodichloromethane demonstrates a significant level of attenuation in all soil types. The clay exhibited the most attenuation followed by silt and then sand. After a period of 50 years, the constituent is at near-zero concentration below a depth of 23 ft (7 meters) in the sand model. The behavior is expected because bromodichloromethane is a constituent with a relatively high adsorption coefficient. Its attenuation is dominated by the sorption by the soil particles.

2.3.2. Chloroform

Chloroform concentration to depth curves are shown in Figures II-2-2A to II-2-2C. Chloroform demonstrates significant attenuation in clay but limited attenuation in silt and sand. After 50 years in the sand and silt models, chloroform is transported beyond the modeled 50 feet (15 meters) of soil with 10 to 30 percent of the original concentration continuing to migrate downwards. In the clay model, the constituent shows a higher attenuation capacity than the other soil types. After 50 years, the constituent is at near-zero concentration at depth of 13 ft (4 meters) of clay and below. Compared to the other constituents, chloroform has a relatively low adsorption coefficient, high Henry's constant, and high diffusion of coefficient in air. The lower adsorption means there is less capacity for chloroform to be sorbed onto soil particles. In addition, the high Henry's constant and high diffusion of coefficient in air allows more volatilization of chloroform into the gas phase where it can migrate more effectively downwards through the vadose zone.

2.3.3. m-Xylene

Concentration to depth curves for m-xylene are shown in Figures II-2-3A to II-2-3C. Significant attenuation of m-xylene is demonstrated in all soil types, with the most attenuation in clay. In the silt and sand models, the concentrations are at near-zero concentrations at a depth of 10 ft (3 meters) after 50 years. In the clay model, concentrations of xylene do not significantly migrate beyond 3 ft (1 meter) after 50 years. Of the four constituents, m-Xylene has the highest adsorption coefficient. The high sorption contributes significantly to the attenuation of m-Xylene.

2.3.4. NDMA

NDMA concentration to depth curves are shown in Figures II-2-4A to II-2-4C. NDMA demonstrates significant attenuation in the soil types modeled. The highest attenuation was observed in the sand followed by silt and clay. The transport behavior of NDMA appears less influenced by sorption in the model compared to the other constituents, which corresponds to its lower adsorption isotherm coefficient. In clays, there is less opportunity for volatilization of NDMA due to higher percent saturation and less air-filled pores as opposed to silt or sand types of soils. Migration in clays is controlled by the downward migration of water. After 50 years, the constituent is at near-zero concentration below a depth of 13 ft (4 meters) in the soil types evaluated in the model.

2.4. Sensitivity Analysis

A sensitivity analysis was performed to evaluate the sensitivity of the model's input parameters. The analysis determines the most important parameters that affect the model's outcome. Input parameters were adjusted to observe the change in effect it would have on the constituent's attenuation. Parameters were adjusted to a range of potential values of the parameter. Many of these parameters are chemical properties.

In this case, the range in each chemical property was derived from a listing of properties for various constituents, which includes most of the known parameters for constituents in recycled water (Alabama Dept of Env. Mgmt, 2008). Table II-2-2 includes the minimum and maximum values for each of the chemical properties evaluated in the sensitivity analysis. The model for bromodichloromethane in a homogeneous sand layer was used as the baseline of this analysis. The baseline's constituent and soil type were arbitrarily chosen. However, any recycled water constituent and soil type would have been appropriate as a baseline for the purposes of this analysis, since the relative change in output is the same regardless of the starting conditions.

2.4.1. Henry's constant

Henry's law constant is an equilibrium constant for a constituent in its aqueous and gas phase. At constant temperature, Henry's law asserts that the concentration of a constituent in the gas phase is proportional to the concentration in the aqueous phase. A constituent with a higher Henry's constant has a higher affinity to the gas phase.

Henry's constant was adjusted to a minimum value of 1.27×10^{-7} (unit-less) and a maximum value of 4.00×10^{0}. The concentration curves of these results are shown in Figure II-2-5. Increasing Henry's constant decreased the attenuation of the constituent. This suggests that more volatile constituents are less likely to be attenuated. In the same respect, decreasing Henry's constant increases the constituent's attenuation in the soil. The explanation for this behavior is that the modeled soil is only partly saturated. Constituents with higher Henry's law constants can effectively migrate through air or water in the subsurface, whereas constituents with lower Henry's law constants are limited to migration through the aqueous phase. In addition, the lower concentration of the constituent in water allows for less adsorption onto soil particles.

2.4.2. Adsorption Isotherm

The adsorption isotherm, K_d, is used to express the equilibrium of the concentration of the constituent in the aqueous phase and the concentration of the constituent sorbed onto organic matter in the soil particles. A constituent with a high adsorption isotherm is has a higher affinity to adsorb to organic matter.

The adsorption isotherm was adjusted to a minimum value of 2.40×10^{-14} m^3/g and a maximum value of 8.80×10^{-3} m^3/g. The concentration curves of these results are shown in Figure II-2-6. As expected, increasing the adsorption isotherm significantly limits the migration of the constituent. In the same respect, decreasing adsorption isotherm significantly decreased the constituent's attenuation in the soil. In this model, adsorption to organic matter contributes significantly to the attenuation of constituents.

2.4.3. Water Transport Models

To evaluate the sensitivity of the selection of water transport model, three alternative models for water transport were applied, including modified van Gunechten, Brooks Corey (1964), and Kosugi (1996). The concentration curves of these results are shown in Figure II-2-7A through II-2-7C. These figures can be compared to Figure II-2-1A, which used the identical inputs for the originally selected water transport model (van Genuchten–Mualem). Of the four water transport models, only the Brooks Corey model shows any significant difference. The other three models have nearly identical results. The Brooks Corey model shows slightly greater attenuation than the other models. Since the results of the originally selected van Genuchten–Mualem model are matched by two other models, and are more conservative than the results from the Brooks Corey model, the original water transport model selection appears to be appropriate.

2.4.4. Molecular Diffusion

The molecular diffusion is the transport of molecules from a region of higher concentration to one of lower concentration. In the vadose zone, the rate of diffusion is proportional to the gradient of concentration. Diffusion of constituents occurs most rapidly in gases and less so in liquids. Diffusion through water may be limited by the saturation in the subsurface, because diffusion requires connected pore spaces filled with water. Conversely, diffusion through air is more effective in unsaturated soils.

The molecular diffusion in air was adjusted to a minimum value of 1.49×10^{-11} m^2/d and a maximum value of 1.30×10^{-1} m^2/d. The concentration curves of these results are shown in Figure II-2-8. Increasing the molecular diffusion in air significantly decreased the attenuation of the constituent. In the same respect, decreasing molecular diffusion in air significantly increased the constituent's attenuation in the soil. This behavior is expected because in the unsaturated zone, diffusion through air can be a significant transport mechanism particularly to highly volatile constituents. In this model, the molecular diffusion in air is a significant factor in the attenuation of constituents.

The molecular diffusion in water was adjusted to a minimum value of 1.04×10^{-5} m^2/d and a maximum value of 1.47×10^{-4} m^2/d. In general, values of the diffusion coefficient for water do not vary as significantly as the diffusion coefficient for air. The concentration curves of these results are shown in Figure II-2-9. Increasing and decreasing the molecular diffusion in water within this range did not significantly change the attenuation of the constituent.

2.4.5. Bulk Density

The bulk density of soil is the mass of the soil particles divided by the total volume occupied by the soil. Bulk density of soil is typically between 62 and 124 pcf. The bulk density was adjusted to this minimum and maximum value in the model to observe the effect on the results. The concentration curves of these results are shown in Figure II-2-10. Increasing the bulk density slightly increased the attenuation of the constituent. In the same respect, decreasing bulk density slightly decreased the constituent’s attenuation in the soil. Based on these observations, bulk density does not appear to significantly affect attenuation of constituent concentrations.

2.4.6. Heterogeneity in Soil Profile

The previous model scenarios were constructed as homogeneous sand, silt, or clay soil profiles. However, at most locations within the project study area, soil is heterogeneous with respect to depth and soil profiles are composed of layers of different soil types. To evaluate the potential effect of heterogeneity on the model results, a scenario was developed that included a distribution of soils in the subsurface.

The heterogeneous soil profile used in this scenario consisted of alternating 10-ft layers of sand and clay. The 0 to 10 ft, 20 to 30 ft, and 40 to 50 ft depths were layers of sand. The 10 to 20 ft and 30 to 40 ft depths were layers of clay. The concentration curve of this model is shown in Figure II-2-11. The bromodichloromethane exhibited a sharper decline in concentration at the 10 foot depth where a clay layer was introduced. This is expected as the clay exhibited a higher level of attenuation than the sand. Attenuation in this case is more prominent than in the case of sandy soil (Figure II-2-1A) and less prominent in the case of clayey soil (Figure II-2-1C).

2.5. Conclusions

The modeling shows that concentrations of some constituents are attenuated under certain simulated conditions of irrigation with recycled water with a modeled 50-foot vadose zone. The model verifies that constituents generally attenuate better in clayey soils than sandy or silty soils. Attenuation is most greatly achieved by constituents that have transport processes dominated by low volatilization and high sorption. Because the model is a closed system (i.e. constituents cannot be lost through escape to the atmosphere), volatilization may enhance the migration of a constituent downward. Constituents such as NDMA, which are relatively less prone to volatilization, may actually be transported more quickly through clayey soils. Beyond the 50-year time mark, the constituent concentrations will continue to progress towards the irrigated concentrations along the entire depth profile. This is because adsorption to organic matter has a fixed capacity, and given enough exposure to the constituent, the soil will eventually become saturated and sorption will essentially be nullified. However, on this time frame, the processes of degradation which were not considered in this model may be significant enough to prevent further migration. Degradation is an important element to the attenuation of recycled water. The level of degradation or transformation is different for each constituent. Evaluations on the contribution from degradation or transformation could not be made due to lack of available data for recycled water constituents.

The sensitivity analysis has shown that the model results are sensitive to certain input parameters. Constituent characteristics including Henry's constant, adsorption isotherm, and the molecular diffusion in air are factors that most significantly determine the constituent's rate of migration to groundwater. In addition, soil type plays an important role in determining which constituents present greater threats to groundwater. The molecular diffusion in water, bulk density, and choice of transport model did not significantly change the model results.

The model is useful as a tool for a preliminary evaluation of constituent transport through the vadose zone, but not appropriate for a detailed site specific evaluation because chemical characteristics are not known for many of the recycled water constituents. Reference values for chemical characteristics such as first-order degradation rate, diffusion coefficients, and so forth are generally limited.

Recommendations for the pilot study based on findings from the model are discussed in Section 4.3.

3. SOIL CORE BENCH TEST

Recycled water commonly contains a number of constituents introduced through the original use of the water, or through the treatment processes that the water undergoes after use. The main focus of the study is chemical constituents, including those of anthropogenic and nonanthropogenic origins. A few constituents of concern are biological. One major goal of this study is to determine whether any of these constituents have the potential to negatively impact groundwater if recycled water is used for irrigation. As one method to evaluate this potential, a bench-scale test was conducted using actual soil samples and recycled water in controlled laboratory conditions. In this section, the soil core bench test and its application to this project are discussed.

3.1. Introduction

The goal of the soil core bench test is to simulate the subsurface fate and transport of recycled water under conditions similar to those expected on sites where recycled water would be used for irrigation. The bench test serves as a controlled environment where the materials and parameters in the test are known. In this environment, recycled water from two different treatment plants and eleven soil cores are selected. By introducing recycled water at the top of the soil core, and measuring the quantity and concentrations of the effluent water at the bottom of the soil core, the estimated loading of each constituent to groundwater was estimated. The effects of the recycled water on the hydraulic conductivity of the soil were also calculated by comparing a final hydraulic conductivity where recycled water is applied to the soil cores and the initial hydraulic conductivity without exposure to recycled water by using ASTM method D-5084.

3.2. Methodology

3.2.1. Soil Cores

Soil cores were collected in eight locations throughout the Santa Clara and Llagas Subbasins. Four locations were selected in each subbasin, representing a geographic distribution over the areas where recycled water is currently being used and may be expanded in the future, and a range of surface soil types. The locations where the drilling occurred are shown in Figures II-3-1 and II-3-2. The IDT site, which is the location of the pilot study to be conducted in the next phase of this project, was one of the four locations in the Santa Clara Subbasin (location 3 on Figure II-3-1). The locations for the soil core collection were chosen within SCVWD easement and right-of-way areas throughout the Santa Clara and Llagas Subbasins.

At each location, two adjacent cores were collected. The first core was opened and logged onsite. The other was capped and saved for potential use as core sections for the bench test. Soil cores were taken from May 12 to 14, 2008. Cores were approximately 1.8 inches in diameter. Due to physical refusal at the drilling site, cores could not be extracted to the planned depth of 30 feet from locations SCV-2 and Llagas-1. Location SCV-2 was completed to a depth of 18 feet, and location Llagas-1 was collected to a depth of 12 feet. At two other locations, Llagas-2 and Llagas-3, a single 30-foot soil core was collected, but a second soil boring could not be collected due to damages to the drill tips. The soil at these locations was logged from the first boring by inspection through the transparent sleeve and at the open ends of each section. Boring logs for all locations are included in Appendix II-A.

3.2.2. Soil Core Section Selection

Of the eight soil cores collected, eleven sections from the undisturbed collected cores were selected for the bench test: three four-foot sections representative of coarse-grained soils, three four-foot sections representative of semi-fine-grained soils, and five one-foot sections representative of fine-grained soils. Four foot sections were the longest continuous sections that could be extracted by the drill rig. In some of these sections, particularly for loose soils, a full four feet of soil was not collected. Some amounts of loose soil were lost at the ends of the sections during lab setup.

Shorter sections of fine-grained soil were chosen for this test to allow more sample water to permeate through within the time frame of the study. Shortening the soil sections is expected to result in less constituent attenuation, however since the attenuation was expected to be higher for fine-grained soils, it could still be measured and evaluated over one foot lengths. The core sections were selected based on the adjacent logged core sections. The core sections representing each soil type were selected to be similar in grain size distribution.

For each selected core section, an additional six-inch segment was collected either directly above or below the section. The segment was analyzed for hydraulic conductivity (by ASTM D-5084) and grain size distribution using sieve and hydrometer analysis. Each segment was similar in composition to its respective soil core by visual inspection. Hydraulic conductivity values obtained from these sections were used to represent initial conditions of the soil prior to exposure to recycled water.

3.2.3. Remolding

In the process of collecting the soil cores through direct-push drilling, small channels were formed between the soil and the sleeve. The channels resulted from the use of a soil-trapping device at the end of the sleeve which is designed to minimize loss of soil as the core is extracted from the borehole. The cores could not be used for the bench test in this condition because the applied recycled water would flow through the channels along the side of the core instead of infiltrating slowly through the soil as would occur in the environment. To eliminate the open channels, each soil core was remolded prior to initiation of the bench test. The moisture content and density of each soil core were measured, and the soil was extracted and fitted into a new sleeve with no channels, maintaining the moisture and density of the original cores. This prevented side percolation as a preferential pathway for water between the soil core and sleeve and ensured that the migration time through the soil cores would be similar to conditions in the field. In the process of remolding, rocks larger than 3/8 inches were removed from the cores to prevent artificial void spaces within the soil cores and ensure a better fit within the sleeves. The remolding process is not expected to create additional preferential pathways or irregular grain distributions. The soil core lengths are expected to decrease slightly due to the removal of the larger sized rocks. However, the effective length of the soil core at which attenuation occurs remains the same because the rocks do not contribute significantly to attenuation. Because the moisture content and density were identical to the original cores, remolding is not expected to change the final hydraulic conductivity of the soil matrix.

3.2.4. Use of Gypsum

The application of gypsum (hydrated calcium sulfate) is commonly used to promote soil hydraulic conductivity which may affect constituent transport to groundwater, especially where recycled water is used for irrigation. Most often, gypsum is distributed on the soil surface in areas of fine-grained soil to improve soil hydraulic conductivity. Because the use of recycled water for irrigation is often accompanied by the use of gypsum to prevent adverse effects to the soil hydraulic conductivity, gypsum is included as an important variable to analyze for the bench test. To measure the effects of gypsum use, an additional one-foot fine-grained soil core section was used to test each recycled water source used in the bench test with gypsum added. Adding gypsum affects soil by lowering the soil's Sodium Adsorption Ratio (SAR). A lower SAR prevents clay swelling. SAR and clay swelling are further discussed in Section 3.3.2.2. Because gypsum specifically affects the clays in soil, the most significant hydraulic conductivity impact due to gypsum application is expected in the fine-grained soil cores. Therefore, only the fine-grained soil cores were used to evaluate the effect of gypsum application. Approximately 0.4 grams of gypsum was applied evenly to the top of each of these sections. This value corresponds to the prescribed product application rate of 50 lb per 1000 square feet.

3.2.5. Water Sources

Two sources of recycled water were used for the bench test: the San Jose/Santa Clara Water Pollution Control Plant (SJ/SC WPCP), and the South County Regional Water Authority (SCRWA) Gilroy plant. SJ/SC WPCP services wastewater treatment to cities in the Santa Clara Subbasin including San Jose, Santa Clara, Milpitas, Campbell, Cupertino, Los Gatos, Saratoga, and Monte Sereno. The SCRWA plant services wastewater treatment to cities in the Llagas Subbasin including Morgan Hill and Gilroy. These two plants cover the areas where recycled water expansion is most likely in the Santa Clara and Llagas Subbasins.

SJ/SC WPCP wastewater is treated in a three step process. Primary treatment takes place in large settling tanks removing 50 percent of the wastewater contaminants in a 24 hour process. Secondary treatment includes aeration and secondary clarifiers. The final step is tertiary treatment involving filtration through filter beds and then gaseous chlorine for disinfection. Pollutants and solid wastes removed from the three treatment steps are directed to anaerobic digesters. The SCRWA plant also treats wastewater in three steps. Primary treatment consists of bar screens and grit chambers which are aerated basins that remove heavy particles. Secondary treatment includes oxidation ditches and secondary clarifiers. The oxidation ditches have aerated and non-aerated zones. Tertiary treatment includes filtration using anthracite media filters and disinfection by sodium hypochlorite. Solids collected from the SCRWA treatment steps are dewatered by belt filter presses. Recycled water from both sources meets Title 22 regulations.

Distilled water was used as a third source, to represent a control for comparison. The control water in the influent monitoring is analogous to a field blank; the water is expected to be clean (no detections of contaminants). Effluent monitoring of the control water is expected to observe detections of some constituents as a result of leaching from the soil. Using the control, the contribution of potential leaching of constituents may be observed and measured. Distilled water was treated with calcium chloride ($CaCl_2$) in order to maintain an ionic strength similar to that of groundwater. The proposed dosage of the additive was 11.1 grams per 10 liters of distilled water. The additive was mixed with the distilled water prior to application on the soil column. Each water source was used on three soil core sections with different soil types: coarse-grained, semifine-grained and fine-grained.

Ideally, the influent water for the bench test would be directly obtained from the recycled water distribution system. However, it was not possible to maintain the bench test at a location where both recycled water sources could be plumbed directly to the bench test. Therefore, recycled water was collected in batches from each of the two source plants, and preserved as well as possible during the execution of the bench test. Recycled water was collected twice from each plant in order to refresh the source water midway through the test. The first sample of each source was collected on May 14, 2008. The second sample of each source was collected on June 12, 2008 to refresh the sources. During the bench test, the recycled water sources were maintained in closed opaque containers above the soil cores in an enclosed cabinet space with minimal exposure to air, to minimize volatilization and photodegradation. The influent sources were connected to the soil cores by plastic tubing, and the application of the influent sources was gravity-driven. Influent water sampling occurred simultaneously to effluent water sampling of the respective coarse grained core. The coarse grain core was selected as it was expected to produce effluent water before the semi-fine and fine grained core. Samples of the influent recycled water collected from the closed opaque containers throughout the bench test indicate that the influent water remained representative of the recycled water sources, and were consistent with previously measured values (see Volume I).

3.2.6. Bench Test Procedures

Figure II-3-3 presents a flow diagram for the bench test apparatus. Recycled water from the SJ/SC WPCP is paired with soil core sections derived from the Santa Clara Subbasin and recycled water from the SCRWA plant is paired with soil core sections derived from the Llagas Subbasin. Thus, each soil core is exposed to the corresponding recycled water source for that area.

Effluent water from each core was monitored twice during the bench test. The first sampling event occurred at first breakthrough for each core section. The second sampling event for each core started immediately after completion of the first sampling event. The separation between the first and second sampling for a given constituent was 8.2 liters; this volume is the combined sample volume requirement for all of the constituents to be tested (Table II-3-1). Based on the measured pore volumes for each core, 8.2 liters equates to 9.3 to 40 pore volumes based on the porosity of the soil cores. A pore volume refers to the total amount of void space in the soil column. A higher pore volume between sampling of a constituent was desired so that changes in attenuation over time could be observed. As more pore volumes of recycled water are passed through the soil core, the system better represents longer term conditions. Due to the different hydraulic conductivity of each soil, sampling events for each core did not occur at the same time.

Sample bottles were filled for each analysis in a specific order prioritized by a constituent of concern list shown in Table II-3-1. The constituents to be monitored in the bench test were selected based on their potential to be present in recycled water and their potential to negatively impact groundwater. This evaluation was conducted in the previous phase of this project (see Volume I of this report). Aldicarb sulfoxide, PHaCs, NDCs, NBBS, and trisphosphates which were recommended for further monitoring from Volume I were not included in the bench test as a commercial laboratory to test for these constituents could not be identified. While these constituents were not monitored, the constituents that were part of the monitoring plan in the bench test are of a wide characteristic range that confidently represents recycled water. VOCs, which were not recommended for further monitoring in Volume I, were included in the bench test because the VOCs are a part of the analysis (EPA 8260B) that also analyzes THMs. In addition, bromide was included in the sampling list as a tracer.

During sampling, sample bottles were filled as the volume of the effluent water reached the required volume for the next analysis. Six out of the eleven soil cores sections completed the full sampling objectives. Due to extremely low final hydraulic conductivity, the remaining soil core sections were unable to yield a complete sample for all constituents. Irrigation of cores for the bench test began on June 8, 2008, and continued through October 8, 2008.

During the bench test, all portions of the apparatus were sealed to prevent exposure to air and light. Water sources were covered and effluent water was collected in amber glass jars to prevent volatilization and photodegradation. A record was maintained of the water volume that passed through each core section over time. Using Darcy's law and this information, the final hydraulic conductivity of each soil core section was determined during the bench test.

3.2.7. Analytical Laboratories

Laboratory analysis of the water samples were conducted by a combination of four laboratories: Weck Laboratories, MWH Laboratories, EMLab P&K, and Cranmer Analytical Laboratory. The specific laboratories performing each analysis and the corresponding analytical methods are listed in Table II-3-1.

3.2.8. Hydraulic Conductivity

Hydraulic conductivity tests were conducted to determine the effects of recycled water on soil permeability. Hydraulic conductivity of the soil was determined prior to recycled water application by ASTM D-5084, Method C: Falling Head, Rising Tailwater Elevation (herein referred to as initial hydraulic conductivity). The hydraulic conductivity of each soil sample was also estimated during the bench test using Darcy's Law and the recorded times and effluent volumes during the bench test (referred to as final hydraulic conductivity in this report). The main intent of the two sets of data on hydraulic conductivity is to compare the effect of the water source (recycled water versus control water) on the hydraulic conductivity of the soil. The hydraulic conductivity data is also used to compare between different soil cores for each recycled water source.

3.2.9. X-ray Diffraction

To evaluate the potential correlation between initial hydraulic conductivity by ASTM D-5084 and the clay mineralogy of each soil core, samples of each soil core section were analyzed by x-ray diffraction. Of the 11 soil core sections, samples from 10 of those sections were analyzed. Core section SJSC-C was a sample with high coarse grain content and very little fine grains. Due to the low amount of fine grains there was not enough material from that section to perform the diffraction analysis. X-ray diffraction was performed by the UC Davis laboratory at the Land, Air and Water Resources Department. Results of the x-ray diffraction analyses are discussed in Section 3.2.10 along with descriptions of the soil columns.

3.2.10. Soil Core Descriptions

Descriptions of each of the eleven soil cores included in the bench test are provided below. Drilling locations for the Santa Clara Subbasin are shown on Figure II-3-1, and locations for the Llagas Subbasin are shown on Figure II-3-2. Full soil boring logs for each of the cores are included in Appendix II-A. Grain size and hydraulic conductivity analyses are provided in Appendix II-B. The table below provides some details of each soil core. The lengths of the cores are shorter due to some amounts of loose soil lost at the ends of the section. Note that the Santa Clara map location number 3 is the site of the pilot study.

Sample ID	Grain Category	Gypsum Applied?	Subbasin Derived	Map Location Number	Core Length (in)	Depth Extracted (ft)	Water Source Applied	Region type
SJSC-A	Fine	No	Santa Clara	3	12	20 - 24	SJSC WCPCP	Unconfined
SJSC-D	Fine	Yes	Santa Clara	3	12	20 - 24	SJSC WCPCP	Unconfined
SJSC-B	Semi-fine	No	Santa Clara	4	29	0 - 4	SJSC WCPCP	Unconfined
SJSC-C	Coarse	No	Santa Clara	2	28	4 - 8	SJSC WCPCP	Unconfined
SCRWA-A	Fine	No	Llagas	4	12	24 - 28	SCRWA	Confined

Sample ID	Grain Category	Gypsum Applied?	Subbasin Derived	Map Location Number	Core Length (in)	Depth Extracted (ft)	Water Source Applied	Region type
SCRWA-D	Fine	Yes	Llagas	4	12	24 - 28	SCRWA	Confined
SCRWA-B	Semi-fine	No	Llagas	4	33	4 - 8	SCRWA	Confined
SCRWA-C	Coarse	No	Llagas	2	29	0 - 4	SCRWA	Unconfined
DI-A	Fine	No	Santa Clara	1	12	16 - 20	Distilled Water	Confined
DI-B	Semi-fine	No	Llagas	3	46	20 - 24	Distilled Water	Unconfined
DI-C	Coarse	No	Santa Clara	4	34	12 - 16	Distilled Water	Unconfined

3.2.10.1. SJSC-A

SJSC-A is a 12-inch soil core of fine-grained material derived from an unconfined region of the Santa Clara Subbasin. The sample was extracted from between 20 and 24 feet depth at the IDT property located on Silver Creek Valley Road, San Jose (Boring SCV-3). This property was selected because it is the location for the pilot study conducted as the next phase of this project. For comparison with respect to gypsum application, SJSC-A and SJSC-D are soil cores derived from the same location and depth range. Source water used to irrigate this core was tertiary treated effluent from the SJ/SC WPCP.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be, in order of decreasing percentages, kaolinite, vermiculite, smectite, and mica. Minor amounts (5 to 10%) of hydroxy-interlayered 2:1 mineral (HIM) and trace amounts (<5%) of quartz were also found. These results appear to be similar to those from the SJSC-D sample which were derived from the same section, which suggests that the results are reproducible. Of the clay minerals in major abundance, smectite is the most expansive. Vermiculite and mica can be expansive and kaolinite is generally nonexpansive (Nelson et al., 1997).

Due to the low final hydraulic conductivity with recycled water applied, very little effluent water was available from the SJSC-A soil core for chemical analysis. This resulted in incomplete analytical results as the collected volume of effluent water was sufficient only for analysis using handheld monitoring instruments (DO, ORP, pH, and chlorine). Due to the lack of water infiltration through the soil core, the soil acted as an effective physical barrier to recycled water infiltration within the time frame of the bench test (120 days). Bacterial growth may have also contributed to the reduced flow, although there was not enough effluent to test for bacterial growth.

3.2.10.2. SJSC-B

SJSC-B is a 29-inch soil core of semifine-grained material derived from an unconfined region of the Santa Clara Subbasin near the intersection of San Felipe Road and Bowery Lane, San Jose, CA (Boring SCV-4). The sample was extracted from between 0 and 4 feet depth from this soil boring. Source water used to irrigate this core was tertiary treated effluent from the SJ/SC WPCP.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be, in order of decreasing percentages, kaolinite, mica, and vermiculite. Minor amounts (5 to 10%) of smectite and quartz were also found. Vermiculite and mica, which can be expansive, may have contributed to the lack of flow through SJSC-B. Kaolinite, which was the dominant clay mineral, is generally nonexpansive (Nelson et al., 1997).

Due to the low final hydraulic conductivity with recycled water applied, very little effluent water was available for chemical analysis. This resulted in incomplete analytical results as the collected volume of effluent water was sufficient only for analysis using handheld monitoring instruments (DO, ORP, pH, and chlorine). Due to the lack of water infiltration through the soil core, the soil acted as an effective physical barrier to recycled water infiltration within the time frame of the bench test (120 days). Bacterial growth may have also contributed to the reduced flow, although there was not enough effluent to test for bacterial growth.

3.2.10.3. SJSC-C

SJSC-C is a 28-inch soil core of coarse-grained material derived from an unconfined region of the Santa Clara Subbasin, near the intersection of Virginia Road and Bucknam Ave, Campbell, CA (Boring SCV-2). The sample was extracted from between 4 and 8 feet depth from this soil boring. Source water used to irrigate this core was tertiary treated effluent from the SJ/SC WPCP.

X-ray diffraction was not performed for this soil sample, because there was insufficient clay material for this analysis. Because of the relatively high final hydraulic conductivity of this core, both rounds of analytical sampling were completed within 203 hours.

3.2.10.4. SJSC-D

SJSC-D is a 12-inch soil core of fine-grained material derived from an unconfined region of the Santa Clara Subbasin, at the IDT site property, San Jose, CA (Boring SCV-3). The sample was extracted from between 20 and 24 feet depth from this soil boring. Gypsum was added to this soil core as described in Section 3.2.4. SJSC-A and SJSC-D are soil cores derived from the same location (SCV-3) and depth range (20 to 24 ft). Source water used to irrigate this core was tertiary treated effluent from the SJ/SC WPCP.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be, in order of decreasing percentages, kaolinite, smectite, chlorite and mica. Minor amounts (5 to 10%) of vermiculite, hydroxy-interlayered 2:1 mineral (HIM), and quartz were also found. These results are similar to those from the SJSC-A sample which was derived from the same soil core section. Because of the relatively high final hydraulic conductivity of this core, both rounds of analytical sampling were completed within a 17.5 hour time frame. The quick percolation flow through the soil core is attributed to the addition of gypsum.

3.2.10.5. SCRWA-A

SCRWA-A is a 12-inch soil core of fine-grained material derived from a confined region of the Llagas Subbasin. The sample was extracted from between 24 and 28 feet depth from the soil boring collected near the intersection of Bolsa Road and Bloomfield Ave, Gilroy, CA (Boring Llagas-4). SCRWA-A and SCRWA -D are soil cores derived from the same location (Llagas-4) and depth range. Source water used to irrigate this core was tertiary treated effluent from the SCRWA treatment plant in Gilroy, CA.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be, in order of decreasing percentages, smectite and kaolinite. Minor amounts (5 to 10%) of vermiculite and trace amounts (<5%) of quartz and mica were also found. These results are similar to those from the SCRWA-D sample which was derived from the same soil core section, which supports the reproducibility of the x-ray diffraction data. Smectite is highly expansive and likely contributed to the low flow through SCRWA-A. The kaolinite is generally nonexpansive.

Due to the low final hydraulic conductivity, effluent water did not completely migrate through the soil core within the time frame of the bench test (120 days). This resulted in no chemical analytical results for the first or second event. The soil acted as an effective physical barrier to recycled water infiltration within the time frame of the bench test (120 days). Bacterial growth may have also contributed to the reduced flow, although there was not enough effluent to test for bacterial growth.

3.2.10.6. SCRWA-B

SCRWA-B is a 33-inch soil core of semifine-grained material derived from a confined region of the Llagas Subbasin near the intersection of Bolsa Road and Bloomfield Ave, Gilroy, CA (Boring Llagas-4). The sample was extracted from between 4 and 8 feet depth from this soil boring. Source water used to irrigate this core was tertiary treated effluent from the SCRWA treatment plant in Gilroy, CA.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be, in order of decreasing percentages, smectite, kaolinite, mica, and vermiculite. Hydroxy-interlayered 2:1 mineral (HIM) and quartz were also found in trace amounts (<5%). Because of the relatively high final hydraulic conductivity of this core, both rounds of analytical sampling were completed within 63 hours potentially due to an overall lower percentage (11%) of clay in the soil.

3.2.10.7. SCRWA-C

SCRWA-C is a 29-inch soil core of coarse-grained material derived from an unconfined region of the Llagas Subbasin near the intersection of Church Ave and Llagas Ave, Morgan Hill, CA (Boring Llagas-2). The sample was extracted from between 0 and 4 feet depth from this soil boring. Source water used to irrigate this core was tertiary treated effluent from the SCRWA treatment plant in Gilroy, CA.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be, in order of decreasing percentages, smectite, chlorite, and kaolinite. Minor amounts (5 to 10%) of mica, hydroxy-interlayered 2:1 mineral (HIM), quartz, and feldspar were also found. Although expansive type clays such as smectite comprised the majority of clay minerals in this soil, the overall percent composition of clay in the soil was very low (the associated soil sample used for the hydrometer test actually revealed zero percent clay). However, there was sufficient clay content to complete the x-ray diffraction analysis. Therefore, clay swelling did not significantly impede the water flow. Because of the relatively high final hydraulic conductivity of this core, both rounds of analytical sampling were completed in 6.4 hours.

3.2.10.8. SCRWA-D

SCRWA-D is a 12-inch soil core of fine-grained material derived from a confined region of the Llagas Subbasin near the intersection of Bolsa Road and Bloomfield Ave, Gilroy, CA (Boring Llagas-4). The sample was extracted from between 24 and 28 feet depth in this soil boring. Gypsum was added to this soil core as described in Section 3.2.4. SCRWA-A and SCRWA -D are soil cores derived from the same location and depth range. Source water used to irrigate this core was tertiary treated effluent from the SCRWA treatment plant in Gilroy, CA.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be smectite and kaolinite, in order of decreasing percentages. Minor amounts (5 to 10%) of mica and vermiculite and trace amounts (<5%) of quartz were also found. Like soil core SCRWA-A, low flow would be expected but for the addition of gypsum. Because of the relatively high final hydraulic conductivity of this core, both rounds of analytical sampling were completed within 2.4 hours.

3.2.10.9. DI-A

DI-A is a 12-inch soil core of fine-grained material derived from a confined region of the Santa Clara Subbasin near the intersection of Tasman Dr. and Cisco Way, San Jose, CA (Boring SCV-1). The sample was extracted from between 16 and 20 feet depth from this soil boring. Source water used to irrigate this core was distilled water. This soil core had the lowest percentage of coarse-grained material of all eleven soil cores. Only 1.9 percent was categorized as sand, with silt (79.1%) and clay (19.0%) comprising the remainder.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be chlorite and kaolinite, in order of decreasing percentages. Minor amounts (5 to 10%) of smectite, vermiculite, hydroxy-interlayered 2:1 mineral (HIM), and trace amounts (<5%) of quartz were also found. Although present only in relatively minor amounts, the smectite and vermiculite may have contributed to clay swelling, reducing flow through the soil core. Bacterial growth may have also contributed to the reduced flow, although there was not enough effluent to test for bacterial growth.

Due to low final hydraulic conductivity, very little effluent water was available for chemical analysis. This resulted in incomplete analytical results for the first and second event. The collected volume of effluent water was sufficient only for analysis using handheld monitoring instruments (DO, ORP, pH, and chlorine) over a 120-day time frame.

3.2.10.10. DI-B

DI-B is a 46-inch soil core of semifine-grained material derived from an unconfined region of the Llagas Subbasin near the intersection of Thomas Road and Oak Brook Way, Gilroy, CA (Boring Llagas-3). The sample was extracted from between 20 and 24 feet depth from this soil boring. Source water used to irrigate this core was distilled water.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be smectite and vermiculite, in order of decreasing percentages. Trace amounts (<5%) of mica were also found. The smectite and vermiculite content likely contributed to clay swelling, resulting in almost no flow through this soil core. Bacterial growth may have also contributed to the reduced flow, although there was not enough effluent to test for bacterial growth.

Due to low final hydraulic conductivity, no effluent water completely migrated through the soil core within the time frame of the bench test (120 days). This resulted in no chemical analytical results for the first or second event.

3.2.10.11. DI-C

DI-C is a 34-inch soil core of coarse-grained material derived from an unconfined region of the Llagas Subbasin near the intersection of San Felipe Road and Bowery Lane, San Jose, CA (Boring SCV-4). The sample was extracted from between 12 and 16 feet depth from this soil boring. Source water used to irrigate this core was distilled water.

X-ray diffraction of the clay minerals revealed the main composition of the clays to be mica and kaolinite, in order of decreasing percentages. Minor amounts (5 to 10%) of smectite and quartz and trace amounts (<5%) of chlorite and feldspar were also found. Mica and smectite may have contributed to clay expansion but the overall percentage of clay in this soil was very low, resulting in a higher flow volume. Because this core was highly permeable, both rounds of analytical sampling were completed in 4.1 hours.

3.3. Results

The bench test was run from June 9, 2008 to October 8, 2008. Sampling for the bench test was completed between June 9, 2008 and July 7, 2008. Very little effluent water was obtained from July 7, 2008 to October 8, 2008, when the only cores that had incomplete sampling were the low-permeability soil cores.

3.3.1. Physical Results

Before and after the bench test, each soil core was analyzed for a series of physical parameters to quantify the grain size distribution, hydraulic conductivity, and clay mineralogy. Those results are discussed below.

3.3.1.1. Sieve Analysis and Hydrometer Test

Sieve analyses and hydrometer tests were used to provide grain distribution information of the soil samples. Results from the sieve analysis and hydrometer test are shown in Table II-3-2. The laboratory report of these analyses may be found in Appendix II-B. Fine-grained core samples, including SJSC-A, SJSC-D, SCRWA-A, SCRWA-D, and DI-A contained silt and clay ranging from 71.2 to 98.1 percent. Semifine-grained core samples including SJSC-B, SCRWA-B, and DI-B contained silt and clay ranging from 29.1 to 86.9 percent. Coarse-grained core samples including SJSC-C, SCRWA-C, and DI-C contained silt and clay content ranging from 4.9 to 10.7 percent. The categories presented in Table II-3-2 (fine, semi-fine, and coarse) were determined based on initial onsite inspection of borings and boring logs using the USCS classification system. Sieve analysis and hydrometer tests later yielded a different set of soil classifications although overall, the classifications were not extremely different. Revised USCS classifications from the sieve analysis and hydrometer test are presented in Table II-3-2 and applied in this study.

The core samples that yielded little to no effluent water were primarily samples with high silt and clay content. With the exception of DI-B, the silt and clay content of these cores ranged from 82.6 to 98.1 percent. The silt and clay content of DI-B is 29.1 percent, and the clay mineralogy of the DI-B sample was not notably different from the other samples collected from the Llagas Groundwater Subbasin, other than the absence of kaolinite. The clay fraction of sample DI-B was mainly composed of smectite followed by vermiculite.

3.3.1.2. Hydraulic Conductivity

Results for initial and final hydraulic conductivity are shown in Table II-3-2. The original lab report of the tests may be found in Appendix II-B. Final hydraulic conductivity values with recycled water applied could not be obtained for all soil cores. Soil cores that yielded little or no effluent volume can only be qualitatively evaluated. For those cores (SJSC-A, SJSC-B, SCRWA-A, DI-A, DI-B), an estimated maximum final hydraulic conductivity was calculated based on a single pore volume migrating through the core within the 120-day period of the bench test.

Samples with a relatively low initial hydraulic conductivity include SJSC-A, SJSC-B, SCRWA-A, SCRWA-B, and SCRWA-D having a range of 10^{-8} to 10^{-5} centimeters per second (cm/sec). Based on the sieve analysis and hydrometer test, these soils cores tended to contain a higher percentage of fine grains. Samples with higher initial hydraulic conductivity include SJSC-D, SCRWA-C, DI-A, DI-B, and DI-C having a range of 10^{-4} to 10^{-2} cm/sec. These soil samples tend to have higher coarse grain content, although DI-A and SJSC-D are outliers which have relatively high silt content and high hydraulic conductivity.

The initial hydraulic conductivity of SJSC-A and SJSC-D soil, which were derived from the same soil section, varied significantly. The hydraulic conductivity values are two orders of magnitude different (4.70×10^{-6} cm/sec for SJSC-A and 3.10×10^{-4} cm/sec for SJSC-D) which indicates that soil collected from the same core can be variable. However, SCRWA-A and SCRWA-D are derived from the same soil core section and the respective hydraulic conductivities are within the same order of magnitude of each other which indicates a more homogenous soil column.

The addition of gypsum greatly increased the hydraulic conductivity of the samples with exposure to recycled water. Fine soil cores with the added gypsum (SJSC-D and SCRWA-D) yielded sufficient effluent volume for both rounds of sampling events whereas the respective fine soil cores without gypsum (SJSC-A and SCRWA-A) did not. The final hydraulic conductivity of the soil cores with gypsum after recycled water application behaved more similarly to that of coarse grained soil cores, with final values of 1.40×10^{-2} and 8.15×10^{-2} cm/sec for SJSC-D and SCRWA-D respectively.

For soil cores that yielded sufficient water to complete the sampling events, the final hydraulic conductivity after recycled water application is greater than the results derived from the initial hydraulic conductivity by ASTM D-5084. The value of the final hydraulic conductivity after recycled water application during the bench test ranged from 10^{-3} to 10^{-1} cm/sec while initial hydraulic conductivity by ASTM D-5084 ranged from 10^{-7} to 10^{-3} cm/sec. This includes but is not exclusive to cores with gypsum applied. The difference between the two sets of hydraulic conductivity may be partially caused by the different methods used in determining hydraulic conductivity. The final hydraulic conductivity was not determined using the ASTM method, but rather the effluent volume measurements from the bench test. The final conductivity, however, does provide a realistic indication of the observed rate of water percolation.

3.3.1.3. X-ray Diffraction of Clay Minerals

The results of the diffraction of the clay minerals are shown in Table II-3-2 and the original UC Davis analysis report is found in Appendix II-C. Minerals found in main abundance include kaolinite, vermiculite, smectite (montmorillonite), mica, and chlorite. Comparing the samples from the two subbasins, the mineralogy from Llagas Subbasin is more dominated by smectite followed by kaolinite. By comparison, the soil samples from the Santa Clara Subbasin are more dominated by kaolinite. Quartz, which is not a clay mineral, and hydroxy-Interlayered 2:1 Mineral (HIM) were found in a majority of the samples but were found only in trace or minor amounts. Feldspar, which is also not a clay mineral, was found infrequently and in low amounts.

Of the common clays, smectite has the highest capacity for clay expansion followed by illite-vermiculite clays, followed by kaolinite clays (literature review in Volume I). Due to the higher abundance of smectite in the SCRWA samples, more clay expansion is expected in the SCRWA samples than the SJSC samples. Given that gypsum use in conjunction with irrigation is a common best management practice, clay expansion is not expected to contribute to soil aquifer plugging. However, in cases where gypsum is not applied, significant clay expansion can occur, which could reduce infiltration rates and cause surface ponding.

3.3.2. Chemical Results

This section discusses the analytical data of the constituents of recycled water that were observed. Chemical results discussed in this section may be found in Tables II-3-3 to II-3-11. In addition, charts graphically displaying the chemical results are provided in Figures II-3-4 to II-3-48. Original lab reports of the constituent analyses are found in Appendix II-D. Because this evaluation relies on comparison of concentrations in samples collected at the influent and effluent points of each soil core, it became necessary to determine what constitutes a significant reduction in concentration, as opposed to minor concentration differences caused by analytical variability. As a general guideline, concentration differences less than 20% will not be considered as a significant change for the purpose of this bench test. Variability within this range is expected to stem from the analytical procedures used in the bench test. The common level of expected precision for most laboratory analyses is 20%-25%. The actual percentage change is considered when making the comparison for each constituent, so this screening does not dismiss any observed changes in constituent concentrations. The 20% criterion is used only to identify and distinguish significant changes in concentration, as opposed to changes that may be caused by analytical variability.

Of the 11 sample cores, 6 cores yielded sufficient effluent volume to complete two sampling events (SJSC-D, SJSC-C, SCRWA-D, SCRWA-B, SCRWA-C, and DI-C). Cores SJSC-A, SJSC-B, and DI-A yielded only enough volume for a single partial sampling event for constituents that could be monitored by handheld instruments (including DO, ORP, pH, and residual chlorine). Cores SCRWA-A, and DI-B did not yield any effluent volume during the entire course of the bench test.

3.3.2.1. General Water Quality

Alkalinity and pH

The pH did not change significantly between recycled water influent and core effluent samples. Data for pH is graphed in Figure II-3-4. The pH of the recycled water sources were near neutral ranging from 7.3 to 8.1. The pH of the core effluent samples of recycled water ranged from 7.7 to 8.0. For the distilled water source, the influent pH was slightly more acidic, ranging from 6.5 to 7.0 and the effluent pH ranged from 7.3 to 7.9. Because the pH of groundwater is also near neutral, groundwater would not likely be affected due to the pH of these water sources.

Overall Minimum and Maximum Data for pH (pH units) in Soil Columns			
	SJSC	SCRWA	DI
Influent	7.3 - 8.0	7.5 - 8.1	6.5 - 7.0
Effluent	7.7 - 8.0	7.3 - 7.9	7.3 - 7.9

Alkalinity did not change significantly between recycled water influent and core effluent samples. Data for the total alkalinity is graphed in Figure II-3-5. Bicarbonate alkalinity was the main form of alkalinity present in the influent and effluent recycled water samples. Alkalinity as carbonate and alkalinity as hydroxide were at levels below detection in all samples. Data for the separate forms of alkalinity is graphed in Figures II-3-6 to II-3-8. In the control samples, alkalinity was not detected for influent distilled water. In the distilled water effluent samples, bicarbonate was detected as a result of percolation through soil. The total alkalinity in the distilled effluent water samples ranged from 9.5 to 32 mg/L as $CaCO_3$. The alkalinity in the distilled effluent water sample is likely to be a result of leaching from the soil.

Minimum and Maximum Data for Total Alkalinity as $CaCO_3$ (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	160 - 190		240 - 250			ND 2.0 - ND 2.0
Effluent	180 - 180	180 - 200	220 - 340	230 - 240	240 - 240	9.5 - 32

Total Dissolved Solids

Total dissolved solids (TDS) concentrations did not change significantly between recycled water influent and core effluent samples. Data for TDS is graphed in Figure II-3-9. SJSC and SCRWA samples indicate that neither significant leaching (i.e. ion exchange) nor attenuation was occurring.

In the control cores, TDS was not detected in the influent distilled water. In the distilled water effluent samples, TDS was detected as a result of soil dissolving into the water from the influent with $CaCl_2$. TDS in the distilled effluent water samples ranged from 964 to 1360 mg/L. It is notable that these values are higher than the influent and effluent concentrations from the cores irrigated with recycled water. These TDS concentrations may have been caused by the addition of $CaCl_2$ to the distilled water source, which was done to make the ionic charge similar to that of groundwater. The influent distilled water was sampled before the addition of the $CaCl_2$. Hence the distilled influent indicates no detection in TDS and the interpretation of the results accounts for the addition of $CaCl_2$.

Flags that were encountered in the TDS results include the “C” flag. A discussion of the “C” flag is found in Section 3.4. Duplicate data indicate that the “C” flag did not significantly lower the quality of the data.

Minimum and Maximum Data for Total Dissolved Solids (mg/L)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	649 - 690		714 (C) - 725			ND 10 - ND 10
Effluent	701 - 705 (C)	700 - 723 (C)	593 – 625	691 - 699 (C)	585 - 768 (C)	964 (C) - 1360

Dissolved and Total Organic Carbon

Data for dissolved and total organic carbon is graphed in Figures II-3-10 and II-3-11 respectively. In the first sampling round for most soil cores, dissolved organic carbon (DOC) and Total Organic Carbon (TOC) exhibited a large increase in the core effluent concentration. In the second round of sampling, the change in these parameters through the soil cores was low. The data suggest that the soil samples initially leached organic carbon into the water, which was observed in the initial sampled core effluent. By the second round, leaching of organic carbon subsided and effluent concentrations equilibrated to influent concentrations.

DOC and TOC were similar in concentration for SCRWA influent ranging from 4.0 to 4.4 mg/L. The effluent concentrations for SCRWA recycled water in the first sampling round ranged from 11 to 24 mg/L for DOC and 23 to 84 mg/L for TOC. In the second sampling round, the DOC and TOC effluent concentrations for SCRWA water samples ranged from 3.5 to 4.9 mg/L, similar to the influent concentrations. This behavior was also observed in the SJSC and DI samples.

SJSC-C, a coarse-grained soil core, is an exception because the effluent concentrations observed in the first and second sampling round exhibited no significant change. This soil core contained the highest percentage of coarse-grained material, and therefore it most likely did not contain significant organic carbon content.

Minimum and Maximum Data for Total Organic Carbon (TOC) (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	6 - 6.9		4 - 4.2			ND 0.30 - ND 0.30
Effluent	5.9 - 6.7	6.4 - 50	4.3 - 23	4.3 – 84	4.9 - 35	0.68 - 44

Minimum and Maximum Data for Dissolved Organic Carbon (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	5.9 - 7		4.1 - 4.1			ND 0.30 - ND 0.30
Effluent	6 - 6.2	6.3 - 37	3.5 - 11	4.4 – 24	4.3 - 16	0.53 - 13

Redox Potential and Dissolved Oxygen

Oxidation reduction potential (ORP) showed reduction in all soil cores. Data for ORP is graphed in Figure II-3-12. The ORP of both the SJSC and SCRWA recycled water samples ranged from +217 to +417 milliVolts (mV) for the influent and from +123 to +172 mV for the core effluent. In the control samples, the behavior is similar. The ORP of the distilled water ranged from +245 to +297 mV in the influent and from +132 to +195 mV in the effluent. ORP data suggest that there were not major shifts in redox conditions. Positive ORP indicates conditions that favor oxidation reactions such as with oxygen. Negative ORP indicates conditions that favor chemicals to be reduced.

Overall Minimum and Maximum Data for Oxidation Reduction Potential (mV)			
	SJSC	SCRWA	DI
Influent	221 - 417	217 - 230	245 - 297
Effluent	149 -171	123 - 172	132 - 195

Dissolved oxygen (DO) concentrations did not change significantly between influent and effluent recycled water samples. Data for DO is graphed in Figure II-3-13. The majority of the DO data of the recycled water sources for the influent and core effluent samples and control water ranged from 8.1 to 8.7 mg/L. The two exceptions to this case are SCRWA-B and DI-C. In the second sampling round, the SCRWA-B and DI-C effluents observed DO concentrations of 5.3 and 4.2 mg/L, respectively. Overall, the data indicates that the system maintained oxic conditions.

Overall Minimum and Maximum Data for Dissolved Oxygen (mg/L)			
	SJSC	SCRWA	DI
Influent	0.040 - 8.6	8.3 - 8.7	8.3 - 8.6
Effluent	8.3 - 8.6	5.3 - 8.5	4.2 - 8.7

3.3.2.2. Anions and Cations

Chloride

Chloride exhibited no significant change in concentration through any of the soil cores. Data for chloride is graphed in Figure II-3-14.

Chloride was not detected in the distilled water source, but was detected in the effluent. The presence of chloride in the effluent is likely caused by the addition of $CaCl_2$ to make the ionic charge of the distilled water source similar to groundwater. Chloride in the distilled effluent water samples ranged from 230 to 450 mg/L. The influent distilled water was sampled before the addition of the $CaCl_2$. Hence the distilled influent indicates no detection in chloride. The interpretation of the results accounts for the addition of $CaCl_2$. Further discussion of the quality control can be found in Section 3.4.

Minimum and Maximum Data for Chloride (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	190 - 210		220 – 230			ND 0.50 - ND 0.50
Effluent	210 - 210	180 - 200	200 - 210	210 - 210	210 - 210	230 – 450

Sulfate

Sulfate generally exhibited no significant change in concentrations between influent recycled water and core effluent samples with the exception of SJSC-D and SCRWA-D. Data for sulfate is graphed in Figure II-3-15. SJSC-D and SCRWA-D, both fine grain soil cores with added gypsum, exhibited an increase in the first round of sampling followed by concentrations similar to the influent in the second round of sampling. With the exception of SJSC-D, SJSC influent and effluent samples remained similar ranging from 94 to 100 mg/L as SO_4. With the exception of SCRWA-D, SCRWA influent and effluent samples remained similar ranging from 81 to 95 mg/L as SO_4. The initial increase in sulfate in SJSC-D and SCRWA-D is likely a result of the sulfate introduced by the gypsum (hydrated calcium sulfate) as it was broken down into calcium and sulfate ions.

In the control samples, sulfate was not detected in the influent distilled water, but was detected in the effluent of the DI-C sample, as a result of leaching from the soil into the water. Sulfate in the distilled effluent water samples ranged from 3.0 to 5.3 mg/L as SO_4.

Minimum and Maximum Data for Sulfate as SO_4 (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	94 - 100		81 - 82			ND 0.50 - ND 0.50
Effluent	100 - 100	97 - 140	89 - 92	89 - 92	95 - 130	3 - 5.3

Bromide

Bromide was below detection in the influent and effluent samples. The laboratory reporting limit is 0.50 mg/L. Data for bromide is graphed in Figure II-3-16.

Minimum and Maximum Data for Bromide (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C

Cyanide

Cyanide was below detection in the influent and effluent samples. The laboratory reporting limit is 5 µg/L. Data for cyanide is graphed in Figure II-3-17.

Minimum and Maximum Data for Total Cyanide (µg/L)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	ND 5.0 - ND 5.0		ND 5.0 - ND 5.0			ND 5.0 - ND 5.0
Effluent	ND 5.0 - ND 5.0	ND 5.0 - ND 5.0	ND 5.0 - ND 5.0	ND 5.0 - ND 5.0	ND 5.0 - ND 5.0	ND 5.0 - ND 5.0

Boron

Boron concentrations in influent and effluent samples were not significantly different, indicating that the soil cores had minimal effect on this constituent. Data for boron is graphed in Figure II-3-18. Boron in SJSC recycled water influent ranged from 440 to 480 µg/L and boron in the associated soil core effluents ranged from 430 to 440 µg/L. Boron in SCRWA recycled water samples ranged from 360 to 430 µg/L in the influent and 350 to 400 µg/L in the core effluent. In the control sample, boron was not detected in the influent distilled water. Boron was detected in the distilled water effluent, presumably as a result of soil leaching into the water. Boron in the distilled effluent water samples ranged from 16 to 66 µg/L.

Minimum and Maximum Data for Total Boron (µg/L)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	440 - 480		360 - 430			ND 10 - ND 10

Potassium

Potassium concentrations exhibited significant removal between recycled water influent and core effluent samples. Data for potassium is graphed in Figure II-3-19. Potassium in SJSC recycled water samples ranged from 15 to 17 mg/L in the influent and 9.3 to 12 mg/L in the soil core effluent. Potassium in SCRWA recycled water samples ranged from 27 to 32 mg/L in the influent and 1.1 to 24 mg/L in the effluent. In the SCRWA soil samples, the semifine-grained soil core exhibited the most removal of potassium and the fine-grained soil core with gypsum exhibited the lowest potassium removal.

In the control soil cores using distilled water, potassium exhibited an increase in concentration in the effluent samples likely as a result of concentrations in soil leaching into the water. Potassium in the distilled water influent ranged from below detection to 0.29 mg/L and the potassium in the associated effluent ranged from 0.98 to 1.7 mg/L. The concentrations observed in the control samples were lower than the concentrations observed in the samples with recycled water. Detections in the distilled water samples do not affect the interpretation of the results.

Minimum and Maximum Data for Potassium (mg/l)

Calcium

In the first sampling round for the soil cores irrigated with SCRWA water, calcium increased significantly in the core effluent concentrations. By the second round, the effluent concentrations from these cores had dropped to levels similar to the influent concentrations. Data for calcium is graphed in Figure II-3-20. The data suggest that soil cores initially leached calcium into the water and later reached equilibrium. This was not the case for SJSC samples. Calcium in SJSC core effluent samples exhibited little to no change from the influent.

In the first sampling round, SCRWA soil cores had calcium concentrations ranging from 46 to 54 mg/L in the influent water samples and an effluent concentration range of 62 to 110 mg/L. Calcium in the second round SCRWA core effluent ranged from 51 to 55 mg/L, which was more similar to the influent concentrations. In the SJSC samples, the calcium concentrations ranged from 50 to 54 mg/L in the influent and from 51 to 57 mg/L in the effluent, resulting in no significant change. In the control soil core, calcium was not detected in the influent distilled water, but was detected in the effluent samples of distilled water after migration through the cores. The presence of calcium in the distilled water effluent samples is presumably the result of the $CaCl_2$ additive that was needed to make the ionic charge of the distilled water similar to groundwater. The influent distilled water was sampled before the addition of the $CaCl_2$. Hence the distilled influent indicates no detection in calcium. The interpretation of the results accounts for the additive of $CaCl_2$ and the confidence in the interpretation is not weakened. Further discussion of the quality control can be found in Section 3.4.

Minimum and Maximum Data for Calcium (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	50 - 54		46 - 54			ND 0.10 - ND 0.10
Effluent	57 - 57	51 - 57	51 - 110	52 - 75	55 - 62	64 - 150

Magnesium

Magnesium exhibited a similar behavior to calcium. Concentrations of magnesium in the first sampling round exhibited an initial large increase in the core effluent concentration followed by an insignificant change in the effluent concentration on the second sampling round. Data for magnesium is graphed in Figure II-3-21. The data suggests that soil samples initially leached magnesium into the water, but by the second round, leaching of magnesium subsided and core effluent concentrations equilibrated to influent concentrations. This effect was more pronounced in the SCRWA soil cores than in the SJSC soil cores, although the influent concentrations were similar. This effect was not observed for SJSC-C as magnesium in SJSC-C effluent samples exhibited little to no change from influent concentrations. This is likely due to very low percentage of fine-grained material in the SJSC-C soil core, which resulted in high hydraulic conductivity and less opportunity for leaching.

Magnesium in SCRWA recycled water influent ranged from 27 to 32 mg/L. Magnesium in SCRWA recycled effluent water samples ranged from 34 to 71 mg/L in the first round and from 31 to 35 mg/L in the second round. Magnesium in SJSC recycled water influent ranged from 27 to 30 mg/L. For SJSC-D, the magnesium concentration in the core effluent was 41 mg/L in the first sampling round and 32 mg/L in the second sampling round. The effluent concentration for SJSC-C was consistently 26 mg/L throughout the bench test. In the control soil cores irrigated with distilled water, magnesium was not detected in the influent distilled water, but was detected in the effluent at concentrations ranging from 34 to 40 mg/L. Magnesium in the core effluent samples is interpreted to have been derived from the soil core.

Minimum and Maximum Data for Magnesium (mg/l)

	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	27 - 30		27 - 32			ND 0.10 - ND 0.10
Effluent	26 - 26	32 - 41	32 - 71	35 - 52	31 - 34	34 - 40

Sodium

With the exception of SCRWA-B and SCRWA-C, sodium concentrations exhibited little to no change between the influent and effluent recycled water samples. Data for sodium is graphed in Figure II-3-22. Sodium in SCRWA-B and SCRWA-C exhibited significant removal in the first round and little change in the second round. In the first round of sampling, sodium concentrations decreased from 140 mg/L to a core effluent concentration of 24 mg/L for SCRWA-B and 91 mg/L for SCRWA-C.

Sodium influent concentration in the SCRWA recycled water samples ranged from 140 to 160 mg/L. For SCRWA-B, the effluent sodium concentration was 24 mg/L in the first round and 140 in the second round. For SCRWA-C, the effluent sodium concentration was 91 mg/L in the first round and 140 mg/L in the second round. SCRWA-D exhibited little to no change with effluent concentrations of 140 mg/L in both rounds. Sodium concentrations in the SJSC core soil samples in the influent and effluent exhibited little change, consistently ranging from 120 to 140 mg/L. In the control sample, sodium was not detected in the influent distilled water. In the distilled water effluent samples, sodium was detected as a result of soil leaching into the water. Sodium in the distilled effluent water samples ranged from 14 to 150 mg/L. Sodium in the effluent samples is interpreted to have been derived from the soil cores.

Minimum and Maximum Data for Sodium (mg/l)

Effluent	130 - 140	120 - 130	24 - 140	91 - 140	140 - 140	14 - 150

Sodium Adsorption Ratio

The sodium adsorption ratio (SAR) describes the concentration of sodium relative to calcium and magnesium. A high level of SAR in the influent has the potential to cause clay expansion and reduce hydraulic conductivity. A decrease of SAR in the effluent suggests that sodium ions are replacing calcium and magnesium ions in the inter-particle clay surfaces, which causes clay expansion. A further background discussion of SAR may be found in Section 3.1 of Volume I of this report. SAR in the recycled water influents and soil core effluents are calculated and shown in Table II-3-12. In the soil cores irrigated with SCRWA recycled water, SAR decreased in all of the effluent samples. The SJSC recycled water influent had slightly lower SAR values, and the SJSC soil cores did not significantly affect the SAR values in the infiltrating water.

Soil aquifer plugging by clay expansion is most affected by soil with high clay content. Fine-grained soil cores including SJSC-A and SCRWA-A, which both contained smectite in the clay mineralogy in high abundance, may potentially have undergone clay expansion, although since neither of these cores yielded sufficient water for SAR analysis, this cannot be quantitatively evaluated. Soil cores SJSC-D and SCRWA-D, which also have high clay content but were treated with gypsum, did not significantly change the SAR value of the water. The other recycled water soil cores, including SJSC-C, SCRWA-B, and SCRWA-C, contained a low level of clay content which made these cores less susceptible to soil aquifer plugging. Clay content was 11 percent in SCRWA-B and approximately zero percent in SCRWA-C. In SJSC-C the silt and clay content was 8.2 percent. The influent SAR could not be evaluated in the DI source, as sodium, calcium and magnesium were not detected.

3.3.2.3. Nutrients

Phosphate, Total as P.

Phosphate exhibited significant decreases between influent and effluent samples. Data for phosphate is graphed in Figure II-3-23. In the first and second round of sampling, phosphate in SJSC recycled water samples ranged from 0.44 to 0.54 mg/L as P in the influent and ranged from 0.053 to 0.28 mg/L as P in the core effluent. The first and second round of sampling for the SCRWA samples produced phosphate in the recycled water that ranged from 3.9 to 4.6 mg/L as P in the influent and from below detection to 2.9 mg/L as P in the core effluent. SCRWA-D is an exception that exhibited a concentration of 18 mg/L as P in the second round in the effluent.

In the control soil cores, phosphate was not detected in the influent distilled water, but concentrations were detected in the effluent, presumably as a result of leaching from soil into the water. Phosphate in the effluent from the control soil cores ranged from 0.42 to 0.48 mg/L as P.

Minimum and Maximum Data for Phosphate, Total as P (mg/l)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	0.44 - 0.54		3.9 - 4.6			ND 0.050 - ND 0.050
Effluent	0.26 - 0.27	0.053 - 0.28	ND 0.050 - 0.32	0.46 - 2.3	2.9 - 18	0.42 - 0.48

Nitrate and Nitrite

Data for nitrate and nitrite is graphed in Figures II-3-24 and II-3-25 respectively. Nitrate concentrations decreased across most of the soil cores irrigated with recycled water. In some soil cores, nitrite concentrations increased from the initial influent concentrations. The SCRWA-C and SCRWA-D soil cores were exceptions. SCRWA-C observed little changes in nitrate or nitrite in influent and effluent concentrations in the first round, and SCRWA-D observed no significant change in the nitrite concentrations between the influent and effluent in the first round. Decreases in nitrate can occur as a result of transformation into nitrite and/or sorption to the soil. Given the limitations of the bench test, the individual contribution of each of these mechanisms cannot be determined. Flags that were encountered in the nitrite and nitrate results in the pilot study include the “O-04” and “O-09” flags. A discussion of these flag is found in Section 3.4. Although there is some reduced confidence in the qualified data, the data is still appropriately useful for comparative purposes and is therefore used for evaluation in this study.

Nitrate concentrations for the first and second round of sampling in the SJSC recycled water samples ranged from 7.6 to 9.6 mg/L as Nitrogen (N) in the influent and from below detection to 7.5 mg/L as N in the core effluent (SJSC-C and SJSC-D). Nitrate concentrations in the first and second round of sampling in the SCRWA recycled water influent samples were consistently 3.4 mg/L as N. Nitrate concentrations in the SCRWA core effluent samples ranged from below detection to 3.1 mg/L as N. Based on the first round of sampling, the SCRWA-C soil core observed no significant changes in nitrate concentrations between the influent and effluent samples.

Minimum and Maximum Data for Nitrate as N (mg/L)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C
Influent	7.5 – 9.6 (O-09)		3.4 – 3.4			ND 0.11 - ND 0.11
Effluent	7.4 (O-09)	ND 0.11 (O-09)	2.4 (O-09) – 2.7 (O-04)	3.1 (O-09)	ND 0.11 (O-09)	ND 0.11 (O-09)

Results of the nitrite concentrations are varied. Qualifiers in the data may explain some of the variations observed. Nitrite concentrations in the SJSC recycled water samples ranged from below detection to 1.7 mg/L as N in the influent and from 0.18 to 3.4 mg/L as N in the core effluent. Nitrite concentrations in the SCRWA recycled water influent samples were not detected. Nitrite concentration in the SCRWA-B core effluent sample was 0.23 mg/L as N in the first round and below detection in the second. In the first round, there were no detection for nitrite in the core effluent samples for SCRWA-C and SCRWA-D.

In the control soil cores irrigated with distilled water, nitrate and nitrite were not detected in any of the influent or effluent samples.

3.3.2.4. *Anthropogenic Compounds*

Trihalomethanes (THMs)

In general, THM concentrations (bromodichloromethane, bromoform, chloroform, and dibromochloromethane) in the core effluents were significantly less than concentrations in the influent. Data for THMs is graphed in Figures II-3-26 to II-3-29. Reductions in THM concentrations were observed in the soil cores irrigated with SCRWA recycled water. Of the soil cores irrigated with SCRWA recycled water, semifine-grained soil and fine-grained soil with gypsum resulted in more reduced concentrations than the coarse grain soil core. Bromoform was consistently not detected in any of the SCRWA influent or effluent samples.

THMs in SJSC recycled water influent samples are highly varied. In general, THM influent concentrations in the first round were much higher than the influent concentrations in the second round. Effluent samples exhibited decreases in the first round of sampling and increases in the second round of sampling. However, the effluent concentrations from the SJSC soil cores remained relatively constant while the influent source sample concentrations decreased significantly in the second round of sampling. This observation suggests that the effluent water collected for the second round may have originated from the first round influent sample, delayed by the residence time in the soil core. Another possibility is that the elevated THM concentrations in the initial influent sorbed onto the soil, and later desorbed when it came into contact with the second round influent with lower concentrations.

Some THMs were found to be variable in the duplicate sample. In the SJSC second round influent sample, bromodichloromethane, chloroform, and dibromochloromethane concentrations were found to be significantly different (40 to 47 % difference) compared to the duplicate sample. The greatest numerical difference between the primary sample and the field duplicate was 1.1 µg/L for bromodichloromethane, 1.7 µg/L for chloroform, and 0.34 µg/L for dibromochloromethane. Hence, data comparisons (between influent and effluent data) cannot be confidently made for THMs where the difference is equal to or less than the given discrepancy (of primary sample and field duplicate) for that THM. Interpretations of comparisons of THMs with differences (between influent and effluent data) above the respective discrepancy can be made without reduction in the confidence.

In the control soil cores, THMs were not observed in any of the influent distilled water. THMs were not detected in the effluent samples except for chloroform. Chloroform was detected in the effluent samples ranging from 0.77 to 0.84 µg/L, possibly from cross contamination or from laboratory equipment (chloroform is a common constituent in tap water). Leaching of chloroform from the soil core was not expected. Confidence is reduced in data at or below 0.84 µg/L, however the chloroform concentrations in all other samples were above this value, therefore these low concentrations do not affect the interpretation of the data.

Haloacetic Acids (HAA6)

Effluent concentrations of HAA6, which include bromochloroacetic acid (BCAA), dibromoacetic acid (DBAA), dichloroacetic acid (DCAA), monobromoacetic acid (MBAA), monochloroacetic acid (MCAA), and trichloroacetic acid (TCAA), were mixed in results exhibiting increases and decreases for the core irrigated with SJSC recycled water samples. HAA6 were not detected in any of the influent or effluent samples for cores irrigated with SCRWA recycled water or distilled water. Data for haloacetic acids is graphed in Figures II-3-30 to II-3-36. In the tabulated analytical results, total HAA5 were reported which do not include BCAA.

In the SJSC recycled water samples, the individual influent concentrations of HAA6 varied significantly between the first round and second round of sampling. In the first round sampling, individual HAA6 were detected in the influent including BCAA, DBAA, DCAA, and TCAA. The data indicate variability in the influent concentrations with low and high concentrations found in BCAA, TCAA, and DBAA. Individual influent concentrations of HAA6 ranged up to 15 µg/L as observed for DCAA. Effluent concentrations of individual HAA6 remained constant between the first and second rounds for most cases. Of the individual HAA6, BCAA, DBAA, and DCAA demonstrated some attenuation through the soil cores, and TCAA demonstrated no attenuation at all. Overall, attenuation of HAA6 was not strongly observed in the data.

N-Nitrosodimethylamine (NDMA)

NDMA concentrations in recycled water samples exhibited increases and decreases in the effluent samples. Data for NDMA is graphed in Figure II-3-37. In the SJSC recycled water samples, the influent concentrations of NDMA varied significantly ranging from 112 to 375 ng/L respectively. The effluent concentration of NDMA also varied highly, ranging from below detection to 327 ng/L. The presence of NDMA in the effluent samples at concentrations similar in magnitude to the influent concentrations suggests that there is limited, if any, attenuation of NDMA within the SJSC soil cores.

In the distilled water control sample, NDMA was observed ranging from 4.0 to 8.7 ng/L in the influent and from 7.8 to 8.6 ng/L in the effluent. It is suspected that detections of NDMA originated from the distilled water source and are not a result of sampling or handling procedure. In both rounds, trace amounts of NDMA were detected in the influent which supports distilled water as the origin of the

NDMA. Commercial distilled water was used for this test, which may not be as pure as laboratory-grade blank water. Given this information, it is unlikely that the NDMA analysis is affected in the other soil core samples that use recycled water as an influent source.

In the SCRWA recycled water samples, variability in the influent concentrations in the first and second round samples was low ranging from 4.0 to 4.1 ng/L. The variability in the SCRWA core effluent samples was high, ranging from below detection to 7.3 ng/L. NDMA concentrations in the SCRWA influent are consistent with previously observed concentrations as reported in Volume I of this report.

Volatile Organic Compounds (VOCs)

VOCs (excluding THMs which are discussed above) were generally not detected in the influent or effluent samples. Figures were not prepared for VOCs, however, summary tables of detected VOCs in the bench test are displayed in this section. 2-Butanone was detected in high amounts in some of the core effluent samples and in the DI influent samples. The presence of 2-Butanone in these samples did not originate from the two recycled water sources as there were no detections in the samples from these sources. It is unlikely that 2-Butanone originated from the soil cores because the chemical was found in multiple effluent samples from different soil cores collected throughout the study area. Since 2-Butanone is not a basin-wide contaminant, it does not appear that the soil is the source. The source of the 2-Butanone (also known as methyl ethyl ketone or MEK) is suspected to be one of the ingredients in the glue used to assemble the bench test apparatus, and it is not a constituent of concern for this study. No other parameters were observed in such high amounts, which suggests that this issue is localized only to 2-butanone and that results of other constituents are not impacted.

Toluene, methylene chloride, and chloromethane were also found infrequently in the core effluent samples at levels near the reporting limit. The absence of these constituents in the influent or effluent samples from the control core indicates that these detections are not related to quality control issues. Rather, the data suggest that these low concentrations originated from the soil cores, although they were not detected in all soil core effluents. Since these compounds are not considered potential constituents of recycled water, these detections do not affect the interpretation of the results.

Perfluorochemicals (PFCs)

The three PFCs monitored in this bench test were perfluorobutanoic acid (PFBA), perfluorooctanesulfonate (PFOS), and perfluorooctonoic acid (PFOA). PFCs were generally found at higher concentrations in the soil core effluent samples than in the influent recycled water samples, suggesting poor attenuation. Data for PFCs is graphed in Figures II-3-39 to II-3-41. PFBA and PFOS were not detected in any of the influent samples and were detected only in effluent samples of SJSC-C. The higher concentration of PFCs in the effluent may be the result of transformation from chemical precursors, which include various fluorinated alcohols and other fluorochemicals. Overall, attenuation was not well observed.

PFOA in SJSC recycled water samples ranged from below detection to 109 ng/L in the influent and from 73 to 325 ng/L in the core effluent. PFOA in SCRWA recycled water samples ranged from below detection to 39 ng/L in the influent and from 77 to 120 ng/L in the core effluent. For SJSC-C, PFBA was detected only in the effluent ranging from below detection to 940 ng/L and PFOS was detected only in the effluent ranging from 51 to 572 ng/L.

PFOA was found to be variable in duplicate samples. In the SJSC first and second round influent sample, PFOA was found to be significantly different from the respective duplicate samples (27 to 45%). The greatest numerical difference between the primary sample and the field duplicate was 29 ng/L for PFOA in the second round. Because the maximum variation was found to be 29 ng/L, data comparisons (between influent and effluent data) cannot be confidently made for PFOA where the difference is equal to or less than 29 ng/L. Interpretation of comparisons of PFOA with differences (between influent and effluent data) above the respective variation can be made without reduction in the confidence.

In the control sample, PFOA was the only detected parameter and was reported in the influent at 88 ng/L. PFOA was not detected in the effluent samples. Similar to NDMA, the appearance of PFOA in the influent is suspected to be of minor amounts that are in the DI source. Commercial distilled water was used for this test, which may not be as pure as laboratory-grade blank water. Given this information, it is unlikely that the PFC analysis is affected in the other soil core samples that use recycled water as an influent source. Cross contamination is not a likely cause since the concentration is too high relative to the other results. Analytical variability is not a likely cause since the observed changes in PFC concentrations are greater than the determined analytical variability of 29 ng/L.

Nitrilotriacetic acid (NTA) and Ethylenediaminetetraacetic Acid (EDTA)

EDTA concentrations in recycled water samples were varied in results, exhibiting increases in the SJSC recycled water samples and decreases in some of the SCRWA recycled water samples. NTA was below detection in all influent and effluent samples. The laboratory reporting limit for NTA is 100 µg/L. Data for NTA and EDTA are graphed in Figures II-3-42 and II-3-43 respectively.

EDTA concentrations in SJSC recycled water samples were below detection in the influent and ranged from 100 to 174 µg/L in the effluent, exhibiting an increase in concentrations. However, EDTA was found to be variable in the duplicate SJSC influent sample. The second round influent sample was below detection (laboratory reporting limit 100 µg/L), but the duplicate sample was 159 µg/L. Comparison of data may not be as strong for concentration differences that are 59 µg/L or less. EDTA in SCRWA recycled water samples ranged from 232 to 266 µg/L in the influent and from below detection to 242 µg/L in the effluent. Of the SCRWA soil samples, SCRWA-B exhibited the most removal of EDTA and SCRWA-D yielded no significant change in EDTA. Considering the variability in EDTA, attenuation appears to be limited.

In the distilled water control sample, EDTA was only detected in the second round influent sample at the reporting limit of 100 µg/L. This EDTA detection is within the range of potential analytical variability, but may also be attributed to the commercial distilled water source. The presence of EDTA in the distilled water source at this concentration does not significantly impact the findings for the other soil cores. NTA and EDTA were not detected in any of the control effluent samples.

Minimum and Maximum Data for EDTA (µg/L)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C

Surfactants

Surfactant concentrations in recycled water samples were varied in results exhibiting decreases in the first sampling round of the SJSC recycled water samples and increases in some of the SCRWA recycled water samples. Data for surfactants is graphed in Figure II-3-44. Surfactant SJSC influent concentrations were significantly varied between the first and second round of sampling.

Surfactants in SJSC recycled water influent sampling ranged from 0.21 mg/L in the first round to 0.11 mg/L in the second round. Surfactant SJSC effluent concentrations ranged from 0.090 to 0.12 mg/L. By comparing the influent to effluent samples, these concentrations decreased in the first round and remained relatively constant in the second round. Surfactant concentrations in the SCRWA recycled water influent ranged from below detection to 0.060 mg/L. The SCRWA-C and SCRWA-D soil cores exhibited a slight increase in surfactant concentrations, yielding concentrations ranging from 0.070 to 0.080 mg/L in the core effluents. SCRWA-B exhibited no change having effluent concentrations ranging from below detection to 0.060 mg/L. Surfactants were found to be variable in the SJSC duplicate influent sample. The second round effluent samples were below detection (laboratory reporting limit 0.05 mg/L) and 0.11 mg/L. Comparison of data may not be as strong for concentration differences that are 0.06 mg/L or less. Given the presence of surfactants in the effluent samples at concentrations similar in magnitude to the influent concentrations, attenuation of surfactants is interpreted to be limited.

In the distilled control soil cores, surfactants were not detected in the influent or effluent samples.

Minimum and Maximum Data for Surfactants (MBAS) (mg/L)						
	SJSC-C	SJSC-D	SCRWA-B	SCRWA-C	SCRWA-D	DI-C

Pathogens

Due to the potential for bacterial growth within the soil cores, there was difficulty in evaluating the effect of soil attenuation on these parameters in the bench test format. Although an additive could have been used to inhibit bacterial growth within the cores, it was not applied because of the unknown effect it may have had on the other constituents monitored in the bench test. Data for total coliforms, E. coli., and fecal coliforms are graphed in Figures II-3-46 to II-3-48. Both influent and effluent values of HPC and total coliforms appeared to be affected by bacterial growth, including the distilled water control. Growth in the distilled water control may be a result of bacterial contamination. Factors that can affect the growth of coliform and HPC bacteria include filtration, temperature, disinfectant type and residual, assimilable organic carbon level, corrosion control and pipe material selection (LeChevalier, 2003). In this case, exposure to the organic content in the soil likely contributed to bacterial growth. Results that are affected only included HPC and total coliforms. Bacterial growth may have contributed in reducing the final hydraulic conductivity in the soil cores, although the magnitude of this effect could not be measured.

Fecal coliforms and E. coli which indicate fecal matter were not observed in the influent or effluent water samples with the exception of SJSC-D, where one of the effluent samples observed a fecal coliform concentration of 4 MPN/100mL.

Flags that were encountered in these results in the pilot study include the "C" flag. A discussion of the "C" flag is found in Section 3.4. Duplicate data indicate that the "C" flag did not severely lower the quality of the data.

3.4. Quality Control

3.4.1. Distilled Water Core Samples

Distilled water was used as the water source for the control samples. Recycled water constituents were not expected to be detected in the distilled water samples. It was determined that the commercial distilled water used for the bench test was not a laboratory-grade clean water source. The distilled source water was found to have low concentrations of NDMA, potassium, EDTA, 2-butanone, and PFOA. Of these constituents, NDMA was detected in the distilled water influent for both sample events. The distilled water source is suspected to contain NDMA and PFOA in minor amounts. HPC was also observed in the distilled water source, which is attributed to bacterial contamination. 2-butanone and EDTA were not suspected to originate from the distilled water source. The concentrations of 2-butanone are suspected to be a result of contamination from the bench test equipment. However, since 2-butanone was not observed in any of the recycled water influent samples, it is not considered a constituent of concern for this study. EDTA observed in the distilled water is suspected to be a result of analytical variability.

In the DI-C soil core, some constituents revealed increases in concentration after percolating through the soil core in both events. This can occur as a result of leaching or dissolving of constituents already present in the soil and/or from the bench test equipment. These constituents which were found in the effluent samples include magnesium, potassium, sodium, boron, sulfate, phosphate, 2-butanone, chloroform, alkalinity, DOC, and TOC. Increases in the bacterial counts such as Total Coliforms and HPC were likely due to bacterial growth in the soil core. The appearance of 2-butanone is suspected to originate from the glue used to assemble the bench test apparatus. Low concentrations of chloroform in the effluent from the DI-C soil core are suspected to be the result of contamination from the bench test equipment. Soil leaching of inorganic constituents (such as magnesium, potassium, sodium, boron, sulfate, phosphate, alkalinity) and organic carbon from the soil was expected.

Distilled water influent sampling occurred before a $CaCl_2$ additive was applied. The purpose of the $CaCl_2$ additive was to make the ionic charge of the distilled water similar to groundwater. Although it is not known what the true concentrations of calcium, chloride, and TDS were in the distilled water influent, the interpretation of the results are made given this fact, and the confidence in the interpretation is not weakened. No other constituents, other than calcium, chloride, and TDS are expected to be influenced by the additive. Hence the quality of the distilled water of other constituents is not affected.

3.4.2. Field Duplicate

Field duplicate samples were collected from the SJSC recycled water source on both sampling events. Results for both analyses are shown on Table II-3-5. Comparing the duplicate samples, EDTA, Surfactants, THMs , PFOA, HPC, and Total Coliforms were observed to be significantly variable (over 25% difference). The evaluations for these constituents are made in light of the analytical variability, as discussed in the sections above. Additional laboratory qualifiers were applied to some values, as described on Tables II-3-3 to II-3-11. None of these additional qualifiers significantly affect the interpretation of the results.

3.4.3. Ion Balance Check

Ion balances were calculated for the influent and effluent to check for electroneutrality. Cations considered were potassium, sodium, calcium, and magnesium. Anions that were considered included bicarbonate, chloride, nitrate, nitrite, and sulfate. The majority of the ion balances were acceptable, having a cation to anion ratio between 0.90 and 1.10. Three ion balances were out of this range. These were 1st event SCRWA influent, 1st event SCRWA-B effluent and 2nd event DI-C effluent. The observed unbalanced ions may be due to the staggered nature of the sampling. Due to the time required to collect enough sample volume for analysis, sampling events could not be executed for all analyses at once. The concentration of the ion may have changed during the time delay. Instantaneous sampling of all ion concentrations was not possible with the configuration of the bench test. Overall, ion balances help verify the accuracy of ion concentrations in these samples.

3.4.4. Flags

Below is a discussion of the different flags that appeared in the bench test analytical data and any implications for the qualified data. Data qualified with the following flags is still considered for evaluation in this study, but may have reduced confidence depending on the type of data qualification.

3.4.4.1. "C"

The "C" flag indicates that the sample was analyzed beyond the holding time.

This flag was applied to results for the biological constituents in the SJSC source sample and TDS at several locations. These analyses have relatively short hold times (24 hours for biological analyses and 7 days for TDS). For all biological constituents with the "C" flag, a duplicate sample was also taken. The results showed that the concentrations were still within the same order of magnitude. A duplicate TDS sample at SJSC source, which was analyzed within the hold time, showed that the results for the qualified samples were not significantly different. Overall, the "C" flag does not reduce confidence in data significantly.

3.4.4.2. "Q5"

The "Q5" flag indicates that the sample was received with inadequate chemical preservation, but was preserved by the laboratory. Although the chemical preservation was not sufficient while in transit, the laboratory was able to recover the samples by applying preservation once the samples were received.

This flag is observed only for the terbuthylazine analysis on the SJSC source in the first round and the associated duplicate. Terbuthylazine data in the second round sampling of SJSC source, which was not qualified, is consistent with the qualified data.

3.4.4.3. "O-04" and "O-09"

The "O-04" flag indicates the analysis was performed outside the EPA recommended holding time. The "O-09" flag indicates the sample was received with the EPA recommended holding time expired. In both cases, the analysis was performed outside the EPA holding time. The only difference in the flag is to indicate whether the hold time expired in transit to the laboratory or in the laboratory before the analysis was performed.

These flags were observed on the nitrate and nitrite analyses, which have a 48-hour hold time. After the hold time, nitrate can transform to nitrite and vice versa. Or they can transform into other nitrogen compounds. This effect can be more significant the longer the hold time is expired. Comparing primary sample and field duplicate data (where the primary sample was flagged O-04 and the field duplicate was not qualified), the nitrate and nitrite data were similar indicating that the O-04 flag did not significantly affect the data.

3.4.4.4. "M2"

The "M2" flag indicates the matrix spike recovery was low. The associated blank spike recovery was acceptable.

This flag is observed on endrin aldehyde, an analyte included in same analysis for terbuthylazine. Since the flag is associated only with the result for endrin aldehyde, which is not on the constituent list for evaluation, it does not present significant concern for this study.

3.4.4.5. "L3"

The "L3" flag indicates associated blank spike recovery was above method acceptance limits. A blank spike identifies the performance of the preparation method on a clean matrix that is void of interferences.

This flag is observed on pentachlorophenol, an analyte included in same analysis for terbuthylazine. Since the flag is associated only with the result for pentachlorophenol, which is not on the constituent list for evaluation, it does not present significant concern for this study.

3.5. Conclusions

3.5.1. Soil Hydraulic Conductivity

Comparing the soil hydraulic conductivity data, recycled water effluent flow and time data when exposed to recycled water, shows an increase in two of the soil cores (SCRWA-B and SCRWA-C) and a decrease in one of the soil cores (SJSC-A). This does not include soil cores with gypsum which also affect hydraulic conductivity or distilled water soil cores which were not exposed to recycled water. Generally the results suggest that soil cores with a greater distribution in fine grained material tend to exhibit a reduced hydraulic conductivity when exposed to recycled water. In SJSC-B, SJSC-C, and SCRWA-A, it could not be determined whether exposure to recycled water had reduced the hydraulic conductivity. Only a potential maximum value for final hydraulic conductivity could be measured for SJSC-B and SCRWA-A, and the potential maximum is greater than the initial hydraulic conductivity for these soil cores. The initial hydraulic conductivity could not be measured in SJSC-C, due to the insufficient percentage of fine-grained material.

The clay mineralogy indicated that expansive clays (particularly smectite) were present in a majority of the soil samples which also yielded low hydraulic conductivities. Smectite was the most prevalent component of the clays in SCRWA-D, and the second most prevalent in SJSC-D. The addition of gypsum has a significant effect in increasing the hydraulic conductivity of recycled water through fine grained soils, particularly those with clay mineralogy conducive of clay swelling. This is evident as the fine grained soils cores without gypsum (SJSC-A and SCRWA-A) produced very little effluent water. The respective fine grained soils core with gypsum (SJSC-D and SCRWA-D) produced enough effluent water to complete the sampling objectives. A comparison of the initial hydraulic conductivity by ASTM D-5084 and the final hydraulic conductivity for soil cores SJSC-D and SCRWA-D showed increases in hydraulic conductivity of two and five orders of magnitude respectively. This difference is attributed to the application of gypsum.

For the distilled core samples, it was expected that the initial and final hydraulic conductivity (exposed to distilled water with $CaCl_2$) would be similar. However, the data from the two methods yielded different results. The results indicate that DI-A and DI-B had higher initial hydraulic conductivity compared to the final hydraulic conductivity with exposure to distilled water. DI-C had a lower initial hydraulic conductivity compared to the final hydraulic conductivity with exposure to distilled water. The dissimilarity is attributed to the different methodologies in determining hydraulic conductivity. The final hydraulic conductivity was not determined using the ASTM method, but rather the effluent volume measurements from the bench test. The final conductivity, however, does provide a realistic indication of the observed rate of water percolation.

Bacterial growth was present in almost all the effluent samples as shown in the HPC results. Bacterial growth likely contributed to a lower final hydraulic conductivity with exposure to the recycled and distilled water sources, although this could not be verified.

3.5.2. Constituent Attenuation

The monitored constituents for the bench test can be grouped into categories based on their observed potential to migrate through the soil cores with minimal changes in concentration.

A number of constituents consistently exhibited significant (20% or more) attenuation across the majority of the soil columns. These constituents include potassium, phosphate, nitrate, THMs, and some haloacetic acids (BCAA, DBAA, and DCAA).

Some constituents exhibited consistent significant increases after percolation through soil. Constituents that have shown this behavior include nitrite and PFCs. Nitrite concentrations may be a result of leaching from the soil core, or transformation from the nitrate concentrations. PFC concentrations may be the result of PFC formation from precursors in the source water and the soil. PFCs may also have originated from the soil core; soil testing was not done to see if PFCs were already present in the soil.

Constituents that have exhibited initial large increases in the first round of sampling followed by no significant changes in the second round of sampling include DOC, TOC, calcium, and magnesium. The behavior of these constituents is suspected to be a result of an initial leaching from the soil cores, followed by equilibration with the infiltrating water.

Alkalinity, pH, TDS, DO, boron, chloride, sulfate and sodium exhibited no significant changes after percolation through soil. NDMA also does not appear to be affected by the transport through soil, although concentrations were variable in the influent and effluent. One of the haloacetic acids (TCAA) and EDTA did not show strong removal through the soil cores.

Constituents that have been inconclusive due to significant variation in the influent concentration or high potential for bacterial growth include surfactants, HPC, and coliforms. Minor decreases in surfactant concentrations were observed in the SJSC soil cores, and minor increases in the SCRWA soil cores.

Bromide, cyanide, terbuthylazine, NTA, E. Coli, and perchlorate were not detected in the influent or effluent samples. The reporting limit for bromide was 0.5 mg/L, for cyanide is 5 µg/L, for terbuthylazine is 0.1 µg/L, for NTA is 100 µg/L, and for perchlorate is 4 µg/L. VOCs other than THMs were generally not detected. VOCs that were detected were 2-butanone, toluene, methylene chloride, and chloromethane. Toluene, methylene chloride, and chloromethane were found infrequently in the core effluent samples and at levels near the reporting limit. 2-butanone was found in multiple core effluent samples and is regarded as an artifact from the bench test apparatus.

4. CONCLUSIONS

4.1. Summary of Constituent Risk to Groundwater

Based on the results obtained from the model and the bench test, the constituents of concern for recycled water are categorized into levels of risk: high, medium, and low, representing the relative risk to groundwater. The threat evaluated is relative to the risk of detection or increase in concentration of a constituent in the groundwater. High risk includes constituents that have 1) shown an increase rather than a removal from soil percolation or 2) have not shown short-term significant removal and are not typically present in groundwater (not naturally occurring). Medium risk is the category for constituents that 1) have been found to not be attenuated from percolation in the bench test or model (indicating potential long-term risk), and 2) have been shown in Volume I of this report to have higher concentrations in recycled water than in groundwater. The last category, low risk, is for constituents that 1) have exhibited significant attenuation in the bench test or model, or 2) have not exhibited significant attenuation but have been found in Volume I to be similar in concentration in recycled water and groundwater, or 3) have not been detected in any of the samples in the bench test. ORP, DO, alkalinity, and pH are general parameters which can influence the transport of other constituents. These constituents do not pose a threat to groundwater, and are not categorized in terms of risk. Given the close relationship between nitrate and nitrite, these constituents are linked for the purpose of this categorization.

Constituents	High Risk		Medium Risk	Low Risk		
	1) have shown an increase rather than removal from soil percolation in the bench test	2) have not shown short-term significant removal and are not typically present in groundwater	1) have not attenuated from percolation in the bench test or model, and 2) are typically higher concentrations in recycled water than in groundwater	1) have exhibited significant attenuation in the bench test or model	2) have not exhibited significant attenuation but are similar in concentration in reclaimed water and groundwater	3) have not been detected in any of the samples in the bench test

4.2. Comparison Between Model and Bench Test

In the model, the attenuation of the four constituents evaluated was observed to be consistently present whereas the bench test monitored many more constituents and these results were more variable. In the bench test, some constituents did not show any attenuation or actually increased as they migrated through the soil cores. The bench test also had some significant variability in influent concentrations in recycled water.

The bench test was also less consistent in constituent removal over time. The second round sampling was expected to show removal as a longer term condition (the first round sampling being the initial condition). In the model, level of attenuation improved over time. In the bench test, a higher attenuation over time was not seen due to the high variation in results. However, because of the shorter soil length and shorter time frame evaluated, bench test results were expected to show less change when compared to the model short term results.

The model, which evaluated soil depths to 50 feet, showed significant attenuation of the selected constituents: (m-xylene, chloroform, NDMA, and bromodichloromethane). The bench test evaluated soil cores which varied from 1 foot in length (for fine-grained soil cores) to almost 4 feet in length (for coarse-grained core). If the bench test were over a larger soil depth, we expect the attenuation would be more apparent in the results. Generally, the overall attenuation is expected to be greater with more soil depth, however the majority of the attenuation is expected to occur in the first few feet and the incremental attenuation achieved is reduced with increased soil depth. Degradation and/or transformation of constituents, which were fate and transport processes not included in the model, may have influenced the results of the bench test.

The estimated percent removal of each constituent in the model can be compared to the results from the bench test at the same approximate time and depth. From Figure II-2-2A, chloroform is expected to be reduced to approximately 10% of the original concentration at a depth of 13 feet after 2 months. The bench test showed reductions of around 50%, as observed in Tables II-3-5 and II-3-8, indicating that the model may over-estimate attenuation of chloroform through sand. This comparison cannot be reliably made for the other model scenarios because the two-month curves are too severely sloped to obtain a reliable numeric value.

4.3. Recommendations for Pilot Study

The next phase of this study (to be discussed in Volume III of this report) includes a full-scale pilot study of recycled water application at a site in San Jose. Some of the findings from the modeling and bench test can be used to refine the design of that pilot study, so that it provides more useful data for evaluating the potential impact to groundwater.

Constituents of low risk, particularly constituents that were not detected in the bench test, may not need to be included in the full monitoring scheme. These constituents may be scaled back in the monitoring plan scope in the pilot study (e.g. monitoring only in the source recycled water until they are consistently detected).

Vadose zone wells should be installed at depths that are closer to the surface. The model has shown that attenuation behaves more in an exponential curve becoming asymptotic with respect to depth. Attenuation occurs most dramatically at the first ten feet of depth. The model also showed that significant changes in constituent transport can occur over time, and an extended monitoring program is recommended to evaluate potential long-term effects to groundwater.

LAB LOG: 2514.1

RECEIVED
AUG 1 8 2008
BY:

RE: **Lab Report: Soil Column tests-Job #27011 PO 30-12337**

Enclosed are results for: Samples Received - April 25, 2008

Code	Item	Quantity
	Report includes results for:	
	Effluent Monitoring and Collection	6
19526	Sieve Analysis, ASTM D-422 w/ Hydrometer	11
18572	Hydraulic Conductivity-Flex-wall, ASTM D-5084	10
23524	Additional Monitoring	6
	Tests performed by Cranmer Analytical Lab (24 reports)	90
	Photographs of original 11 samples removed from tubes	

Note: Sample SJ/SC-C was composed of 58.8% rock (+3/8"); there was not enough fine material to perform the hydraulic conductivity or hydrometer tests. Five remaining samples have provided inadequate effluent flow for testing.

Thank you for consulting Vector Engineering for your material testing requirements. We look forward to working with you again. If you have any questions or require any additional information, please call us at 1-530-272-2448.

Sincerely,

Prepared By: Kenneth R. Criley
Technical Director

(Specific Gravity assumed as 2.7)		

COMMENTS:

Site water used as permeant (reference sample ID).

Pore Volume = 228.3 cc; Breakthrough within one minute

Sample sieved over 3/8"; 0% rock removed prior to remolding

After test: Sample uniformly moist, sticky clay.

These results apply only to the above listed samples. The data and information are proprietary and can not be released without authorization of Vector Engineering Inc. By accepting the data and results represented on this page, client agrees to limit the liability of Vector Engineering, Inc. from Client and all other parties claims arising out of the use of this data to the cost for the respective test(s) represented here, and Client agrees to indemnify and hold harmless Vector from and against all liability in excess of the aforementioned limit.

Dear Wes:

Enclosed is a report with the results of the mineral analysis of the clay fractions for the 10 samples from Vector Engineering. Please let me know if you have questions about the results.

Sincerely,

Randy

Randal J. Southard
Professor of Soils

Project name: Locus Technologies

X-ray diffraction methods for 10 soil samples received from Vector Engineering, Inc.

Basics of X-ray diffraction

Samples are irradiated with X-rays of a single wavelength, in this case, Cu Kα radiation. The X-rays cause atoms in the sample to vibrate and re-emit the X-rays, that is, they "scatter" the incident X-rays in all directions. If the atoms are arranged in a regular, periodic pattern (that is, if the sample is crystalline), at certain angles of scatter, the scattered X-rays are in phase and the amplitudes of the scattered X-ray waves add and the scattering produces diffraction. From the diffraction angle, the inter-atomic spacing of the planes of atoms causing the constructive interference during scattering can be calculated from Bragg's Law, $n\lambda = 2d\sin\Theta$, where n is an integer that specifies the "order" of diffraction, λ is the wavelength of the Cu Kα radiation, d is the inter-atomic spacing of the diffracting plane of atoms, and Θ is the diffraction angle. The d-spacings are compared to data libraries of the d-spacings of known minerals. Generally speaking, X-ray diffraction is qualitative. At best, it is semi-quantitative, based on peak intensity. Limitations to quantitative interpretation of diffraction patterns are caused by particle-size distribution within the sample, particle orientation, crystallinity (how regular the atomic pattern) is, and small variations in mineral composition, which is particularly common in the layer silicate clays (e.g., smectite, chlorite, and vermiculite). All of these factors can influence peak intensity. For this reason, precise estimates of clay mineral percentages are not possible, and relative abundance of mineral phases is about as quantitative as we can get.

Preparation of clay fractions

Sub-samples weighing about 15 g were taken from each of the ten < 2-mm sieved soil samples and put into separate 250-mL plastic shaker bottles. The bottles were then filled with approximately 0.001 M Na_2CO_3 solution to a 10-cm height, capped, shaken overnight to disperse the sample, and centrifuged at 750 rpm for 3.0 min. The clays in suspension were decanted into plastic cups and stored for X-ray diffraction analysis. The dispersion, centrifugation, and decanting procedures were repeated three more times on each 15 g sub-sample to separate all of the clays from the silt and sand fractions.

Sample cation saturation pretreatment and glass slide mounting

Clay slides for each of the ten soils were made by placing 6 to 10 drops of the stored clay suspensions onto Nuclepore Track-Etch membranes (Whatman, Inc., Piscataway, NJ) mounted on a fritted glass filtration apparatus. The clays were washed with 1 M $MgCl_2$, 1 M KCl, or 1 M $MgCl_2$ plus glycerol, rinsed with deionized water, and transferred from the membranes to glass petrographic microscope slides. The various cation treatments cause layer silicate interlayer d-spacings to change, allowing identification of the array of mineral phases present. X-ray analyses were made using a Rigaku Ultima IV X-ray diffractometer (Rigaku Corp., Tokyo, Japan) fitted with a curved graphite monochromator to produce Cu Kα radiation. After the initial diffraction analysis, the KCl samples were reanalyzed after a 1-hr 550 °C heat treatment.

CERTIFICATE OF ANALYSIS

Client: Locus Technologies
299 Fairchild Drive
Mountain View, CA 94043
Attention: Norman Wong

Phone: (650) 641-8258
Fax: (650) 960-0739

Report Date: 07/18/08 10:38
Received Date: 07/01/08 09:30
Turn Around: Normal

Work Order #: 8070201

Client Project: 27011-07-3200

NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 07/01/08 09:30 with the Chain of Custody document. The samples were received in good condition. The samples were received at 4.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Locus Technologies 299 Fairchild Drive Mountain View CA, 94043	Report ID: 8070201 Project ID: 27011-07-3200	Date Received: Date Reported:	07/01/08 09:30 07/18/08 10:38

Notes and Definitions

O-04	This analysis was performed outside the EPA recommended holding time.
MS-03	Multiple analyses indicate the percent recovery is out of acceptance limits due to a possible matrix effect.
MS-01	The spike recovery for this QC sample is outside of established control limits possibly due to sample matrix interference.
ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 06/26/08 10:30 with the Chain of Custody document. The samples were received in good condition. The samples were received at 2.7 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Locus Technologies
299 Fairchild Drive
Mountain View CA, 94043

Report ID: 8062667
Project ID: Recycled Water Bench Test

Date Received: 06/26/08 10:30
Date Reported: 07/18/08 10:37

Notes and Definitions

O-04	This analysis was performed outside the EPA recommended holding time.
MS-05	The spike recovery and/or RPD were outside acceptance limits for the MS and/or MSD due to possible matrix interference. The LCS and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.
MS-01	The spike recovery for this QC sample is outside of established control limits possibly due to sample matrix interference.
ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

CERTIFICATE OF ANALYSIS

Client: Locus Technologies
299 Fairchild Drive
Mountain View, CA 94043
Attention: Norman Wong

Phone: (650) 641-8258
Fax: (650) 960-0739

Report Date: 06/30/08 22:02
Received Date: 06/20/08 09:00
Turn Around: Normal

Work Order #: 8062047

Client Project: 27011-07-3200

NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 06/20/08 09:00 with the Chain of Custody document. The samples were received in good condition. The samples were received at 5.3 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

Locus Technologies 299 Fairchild Drive Mountain View CA, 94043	Report ID: 8062047 Project ID: 27011-07-3200	Date Received: 06/20/08 09:00 Date Reported: 06/30/08 22:02

Notes and Definitions

MS-05	The spike recovery and/or RPD were outside acceptance limits for the MS and/or MSD due to possible matrix interference. The LCS and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.
MS-01	The spike recovery for this QC sample is outside of established control limits possibly due to sample matrix interference.
ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

CERTIFICATE OF ANALYSIS

Client: Locus Technologies
299 Fairchild Drive
Mountain View, CA 94043
Attention: Norman Wong

Phone: (650) 641-8258
Fax: (650) 960-0739

Report Date: 07/08/08 11:46
Received Date: 06/18/08 09:00
Turn Around: Normal

Work Order #: 8061838

Client Project: Recycled Water

NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 06/18/08 09:00 with the Chain of Custody document. The samples were received in good condition. The samples were received at 6.3 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

Notes and Definitions

O-09	This sample was received with the EPA recommended holding time expired.
MS-05	The spike recovery and/or RPD were outside acceptance limits for the MS and/or MSD due to possible matrix interference. The LCS and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.
MS-01	The spike recovery for this QC sample is outside of established control limits possibly due to sample matrix interference.
ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.

RE: **Lab Report: Soil Column tests-Job #27011 PO 30-12337**

Enclosed are results for: Samples Received - April 25, 2008

Code	Item	Quantity
	Report includes results for:	
	Effluent Monitoring and Collection	6
19526	Sieve Analysis, ASTM D-422 w/ Hydrometer	11
18572	Hydraulic Conductivity-Flex-wall, ASTM D-5084	10
23524	Additional Monitoring	6
	Tests performed by Cranmer Analytical Lab (24 reports)	90
	Photographs of original 11 samples removed from tubes	

Note: Sample SJ/SC-C was composed of 58.8% rock (+3/8"); there was not enough fine material to perform the hydraulic conductivity or hydrometer tests. Five remaining samples have provided inadequate effluent flow for testing.

Thank you for consulting Vector Engineering for your material testing requirements. We look forward to working with you again. If you have any questions or require any additional information, please call us at 1-530-272-2448.

Sincerely,

Prepared By: Kenneth R. Criley
Technical Director

CASE NARRATIVE

Job Number: 1082582
Sample Site: SJ/SC-1 2514-L
Date Received: 06/30/08

To Whom It May Concern:

The sample referred to above was submitted to Cranmer Analytical Lab for Total and Fecal Coliform analyses. Due to an analyst error, the holding time for this analysis was exceeded. We have taken steps to ensure this problem does not happen in the future. It is not likely this event caused significant discrepancies in the reported values. If you have any questions regarding this project, please do not hesitate to call me. I apologize for any inconvenience this may cause.

Sincerely,

Ken Neely, Laboratory Director

CASE NARRATIVE

Job Number: 6081432
Sample Site: SCRWA-1 2514N
Date Received: 06/25/08

To Whom It May Concern:

The sample referred to above was submitted to Cranmer Analytical Lab for Total Dissolved Solids analyses. Due to an analyst error, the holding time for this analysis was exceeded. We have taken steps to ensure this problem does not happen in the future. It is not likely this event caused significant discrepancies in the reported values. If you have any questions regarding this project, please do not hesitate to call me. I apologize for any inconvenience this may cause.

Sincerely,

Ken Neely, Laboratory Director

Sample Site: SJ/SC 2514L
Date Received: 06/30/08 14:12

To Whom It May Concern:

The sample referred to above was submitted to Cranmer Analytical Lab for Total Dissolved Solids analysis three days after collection. Due to the delay in sample submission, and an analyst error, the holding time for this test was exceeded. We have corrected the problem, and ask that samples be submitted as soon as possible after collection to alleviate this issue in the future. I apologize for any inconvenience this may cause. Please do not hesitate to call me with any questions you may have regarding this project.

Sincerely,

Ken Neely, Laboratory Director

Chemical Report

Vector Engineering
143E Spring Hill Drive
Grass Valley CA 95945

Job Number: 6081501
Date Reported: 07/07/08
Date / Time Received: 07/02/08 14:02
System Number:

Sample Number: 6081501 - 1

Sample Site: SJ/SC-2 2514M
Date / Time Collected: 07/02/08 10:00
Sample Collected By: Vector

Parameter	Analysis Result	Reporting Units	Analytical Method	Date of Analysis	Reporting Limit
MBAS (surfactants)	ND	mg/L	EPA 425.1	07/03/2008	0.05

Sample Number: 6081501 - 2

Sample Site: SCRWA-2 2514O
Date / Time Collected: 07/02/08 10:00
Sample Collected By: Vector

Parameter	Analysis Result	Reporting Units	Analytical Method	Date of Analysis	Reporting Limit
MBAS (surfactants)	ND	mg/L	EPA 425.1	07/03/2008	0.05

Sample Number: 6081501 - 3

Sample Site: DI-2 2514Q
Date / Time Collected: 07/02/08 10:00
Sample Collected By: Vector

Parameter	Analysis Result	Reporting Units	Analytical Method	Date of Analysis	Reporting Limit
MBAS (surfactants)	ND	mg/L	EPA 425.1	07/03/2008	0.05

Note: "ND" means "none detected" (ie, none was found in the sample at or above the reporting limit).

Report Comments #246072

Group Comments

Endrin Aldehyde (EPA 525.2) MS was low and the MS was a Locus Technologies sample. Also, LCS RPDs for 2,4-Dinitrotoluene, Caffeine and Dimethoate were all high. However, EPA 525.2 data is acceptable, based on passing LCS/other QC for the batch.

NDMA detected in the method blank below the reporting MRL. Data is acceptable since detected results are >5 times blank detection (0.62 mg/L) and LCS/other QC also passed acceptance criteria.

Report Comments #245968

Group Comments

Anthracene LCS2 RPD was low and Propachlor MRL recovery was high (EPA 525.2). These compunds have been flaged (L4 and LE respectively). Also, RPD recoveries for 2,4-Dinitrotoluene, 2,6-Dinitrotoluene, Benzo(a)pyrene, Caffeine and Dimethoate were outside of lab acceptance limits. Data for all compounds is acceptable, however, based on passing LCS1 and other QC. MS recoveries for several compounds were outside of acceptance limits as well, but the MS was not a Locus Technologies sample.

NDMA detected in the method blank below the reporting MRL. Data is acceptable since detected results are >10 times blank detection (0.62 mg/L) and LCS/other QC also passed acceptance criteria.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2806260201)

Test: Pentachlorophenol (ML/EPA 525.2)

L3 - The associated blank spike recovery was above method acceptance limits.

(QC Ref#: 2806260202)

Test: Pentachlorophenol (ML/EPA 525.2)

L3 - The associated blank spike recovery was above method acceptance limits.

**Report
Comments
#245234**

Group Comments

MS recoveries for Anthracene, Benzo(a)Anthracene and Benzo(a)pyrene were low. However, data is acceptable based on passing LCS/other QC and the MS was not a Locus Technologies sample.

Report Comments #244538

Group Comments

Surrogate (perylene-d12) recovery for sample D-IC 2514K (2806180026) in EPA 525.2 was low and compounds associated with this surrogate have been flagged (S6). However, data is acceptable since re-analysis concerns the surrogate recovery was likely a matrix interference and other surrogate/QC recoveries did meet method acceptance limits. MS recoveries for DEHP and Butylbenzene were also high, but the MS was not a Locus Technologies sample.

#244246

(QC Ref#: 2806140028)

Test: N-Nitroso dimethylamine (NDMA) (MW/EPA 1625MOD)

(NDMA) See QIR GCMS_247691 No IS detected in sample extract. No indication of NDMA in sample However, due to peak shape, detection limit raised to 10 ng/L.

HD - Sample analysis performed past holding time. Data not acceptable for regulatory compliance.

(QC Ref#: 2806140031)

Test: N-Nitroso dimethylamine (NDMA) (MW/EPA 1625MOD)

(NDMA) See QIR GCMS_247691 No IS detected in sample extract. No NDMA detected in sample however due to chromatography, detection level raised to 10 ng/L NSMA.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 05/21/08 09:00 with the Chain of Custody document. The samples were received in good condition. The samples were received at 3.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

Notes and Definitions

Q-08	High bias in the QC sample does not affect sample result since analyte was not detected
O-09	This sample was received with the EPA recommended holding time expired
O-04	This analysis was performed outside the EPA recommended holding time
B-06	This analyte was found in the method blank, which was possibly contaminated during sample preparation The batch was accepted since this analyte was either not detected or more than 10 times of the blank value for all the samples in the batch
ND	NOT DETECTED at or above the Reporting Limit If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002

RE: Recycled Water
Work Order: MRE0508

Enclosed are the results of analyses for samples received by the laboratory on 05/19/08 17:30. If you have any questions concerning this report, please feel free to contact me

Sincerely,

Leticia Reyes

Leticia Reyes
Project Manager

CA ELAP Certificate # 2682

The Chain(s) of Custody, 3 pages, are included and are an integral part of this report.

The report shall not be reproduced except in full, without the written approval of the laboratory. The client, by accepting this report, also agrees not to alter any reports whether in the hard copy or electronic format and to use reasonable efforts to preserve the reports in the form and substance originally provided by TestAmerica

For Volatile Analysis a trip blank is required to be provided. If trip blank results are not included in the report, then either the trip blank was not submitted or requested to be analyzed.

The reported results were obtained in compliance with the 2003 NELAC standards unless otherwise noted.

Locus Technologies 299 Fairchild Dr Mountain View CA, 94043	Project: Recycled Water Project Number: 27011-07-3200 Project Manager: Norman Wong	MRE0508 **Reported:** 06/02/08 15:44

PROBLEM

① COC says 1L Poly and 250mL Poly for each sample, but we only recieved the 1L Polys.

RESOLUTION

Client Instruction* Per Logan of EMLab - San Bruno: EMLab will analyze, report, and invoice all of the bacterrological analyses directly to the client. TestAmerica should analyze, report, and invoice only the MBAS to the client.

Telephone Number of Client:

Client Contact for Instruction:

Date and Time of Instruction: 5/22/08, 1320

Date & Time Form Given to Sample Control: 5/22/08, 1325

CLIENT SERVICES REP. SIGNATURE:

DATE/TIME: 5/22/08, 1320

*If client does not return call within 24 hours, please route this form to the Laboratory Director.

Report
Comments
#241710

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210352)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)

Q5 - Sample received with inadequate chemical preservation, but preserved by the laboratory.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte, but analyte not present in the sample.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210393)

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Group Comments
Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210405)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)
Perylene-d12(70-130) out of limit
Result out of limits: @525PLUS SURR5251 in sample 2805210405
E6 - Concentration estimated. Internal standard recoveries did not meet method acceptance criteria.

Test: Benzo(a)pyrene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(b)Fluoranthene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(g,h,i)Perylene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(k)Fluoranthene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di(2-Ethylhexyl)phthalate (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Chrysene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Dibenz(a,h)Anthracene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di-N-octylphthalate (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Indeno(1,2,3,c,d)Pyrene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Methoxychlor (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte, but analyte not present in the sample.

Test: Permethrin (mixed isomers) (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Group Comments
Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210360)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)
Perylene-d12(70-130) out of limit
Result out of limits: @525PLUS SURR5251 in sample 2805210360
E6 - Concentration estimated. Internal standard recoveries did not meet method acceptance criteria.

Test: Benzo(a)pyrene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(b)Fluoranthene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(g,h,i)Perylene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(k)Fluoranthene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di(2-Ethylhexyl)phthalate (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Chrysene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Dibenz(a,h)Anthracene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di-N-octylphthalate (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Indeno(1,2,3,c,d)Pyrene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Methoxychlor (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Test: Permethrin (mixed isomers) (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

# of Samples	Tests	Qteline#	Bottles-Qty for each sample, type & preservative if any	UN DOT #	Comments
22	@NDMA		2 1L amber glass +1ml thio (8%)		
22	@525PLUS		2 1L amber glass + 2 ml of 6N HCl	UN 1789	
22	OPO4, OPO4-PO4		1 125 ml poly / no preservative **SHORT HOLDING TIME!!!!!**		
22	@PFC		1 x 125 ml poly		
22	EDTASUB, NTASUB		1 x 125 ml amber glass, no preservative		

Code Status Date Shipped Via Tracking # # of Coolers Prepared By Allen Glover

Group Comments
Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210357)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)
E6 - Concentration estimated. Internal standard recoveries did not meet method acceptance criteria.

Test: Benzo(a)pyrene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(b)Fluoranthene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(g,h,i)Perylene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(k)Fluoranthene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di(2-Ethylhexyl)phthalate (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Chrysene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Dibenz(a,h)Anthracene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di-N-octylphthalate (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Indeno(1,2,3,c,d)Pyrene (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Methoxychlor (ML/EPA 525.2)
S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Test: Permethrin (mixed isomers) (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210356)

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Group Comments

Report revised to include BA flag for naphthalene blank contamination in EPA Method 525.2 results.
Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210408)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)

Q5 - Sample received with inadequate chemical preservation, but preserved by the laboratory.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte, but analyte not present in the sample.

EMLab P&K

Report for:

Mr. Norman Wong
Locus Technologies
299 Fairchild Dr
Mt View, CA 94043

Regarding: Project: 27011-07-3200; Recycled Water
EML ID: 423730

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 05-22-2008

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

Work Order #: 8070220

Client Project: Recycled Water Bench Test

NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 07/02/08 09:00 with the Chain of Custody document. The samples were received in good condition. The samples were received at 5.3 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

The results in this report apply to the samples analyzed in accordance with the chain of custody document. This analytical report must be reproduced in its entirety.

Locus Technologies 299 Fairchild Drive Mountain View CA, 94043	Report ID: 8070220 Project ID: Recycled Water Bench Test	Date Received: Date Reported:	07/02/08 09:00 08/28/08 10:20

Notes and Definitions

MS-05	The spike recovery and/or RPD were outside acceptance limits for the MS and/or MSD due to possible matrix interference. The LCS and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.
MS-01	The spike recovery for this QC sample is outside of established control limits possibly due to sample matrix interference.
ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services.

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002.
